(54) Title: PHOTOGRAMMETRY ENGINE FOR MODEL CONSTRUCTION

(57) Abstract: A system and methods for accessing 2D digital images and 3D geometric models over a network (preferably the Internet) and transforming and composing that media along with 2D digital image and 3D geometric model media, acquired by other means, into enhanced 2D image and 3D model representations for virtual reality visualization and simulation is disclosed. Digital images and models from a network and other sources are incorporated and manipulated through an interactive graphical user interface. A photogrammetric media processing engine automatically extracts virtual sensor (camera) and geometric models from imagery. Extracted information is used by a reconstruction processor to automatically and realistically compose images and models. A rendering system provides real-time visualization and simulation of the constructed media. A client-server processing model for deployment of the media processing engine system over a network is disclosed.

PHOTOGRAMMETRY ENGINE FOR MODEL CONSTRUCTION

CROSS-REFERENCES TO RELATED APPLICATIONS

This application claims priority from U.S. Provisional Patent Application
5 60/090,749, filed June 26, 1998 and incorporates that application herein by reference for all purposes.

BACKGROUND OF THE INVENTION

A parametric solid modeler is an approach to creating geometric models of
3D objects and scenes. Constructive Solid Geometry (CSG) and Boundary
10 Representation (Brep) methods are two fundamental solid modeling methods. CSG uses solid primitive shapes (cones, cylinders, torus, spheres, rectangular prisms, etc.) and boolean operations (unions, subtractions, intersections) to create a solid model. A cylinder subtracted from a cube produces a hole, for instance. Brep methods start with one or more wireframe profiles, and create a solid model by extruding, sweeping,
15 revolving or skinning these profiles. The boolean operations can also be used on the profiles themselves and the solids generated from these profiles. Solids are also created by combining surfaces through a sewing operation. Most commercial solid modeling systems are hybrids combining both CSG and Brep methods to create the desired models.

In a parametric model, each geometric entity has parameters associated
20 with it. These parameters control the various geometric properties of the entities, such as the length, width and height of a rectangular prism, or the radius of a fillet. They also control the locations of these entities within the model. Parameters are changed by the user to create a desired model.

If the task is to construct a 3D model of a scene or object depicted in a
25 sketch or a photograph, the use of a conventional solid modeling system can be an arduous task. This is especially true when producing a texture-mapped model, where the original photograph or other imagery is applied to the derived geometric model. The current process typically involves first creating a 3D geometric model then tediously "cutting and pasting" textures onto the model to add realism. Ultimately, the results are
30 limited by the hand-eye coordination of the user. In short, the current approach and available tools cannot achieve desired levels of geometric accuracy, realism (visual fidelity), are too time-consuming, and require too much skill.

SUMMARY OF THE INVENTION

One application of the graphics system described herein is for visualizing the placement of one or more physical objects in a physical scene. In general, digital images of those one or more physical objects and a digital image of the physical scene are input to the graphics system and the graphic system maps the objects in those images to a three-dimensional geometric model using cues in the digital image or provided as additional inputs. The graphics system then generates an image output that is an image of the geometric model, thereby showing a virtual image of the physical objects in the physical scene without actually moving those physical objects into the physical scene.

One use of the graphics system is for electronic commerce. For example, a consumer captures a digital image of a room in the user's home and provides it to the graphics system. A merchant captures digital images of products it has for sale. Thus, the graphics system can combine the images to show the consumer an image of what the product might look like within the room where the user might place the products, if purchased.

If the user cannot capture all of the room in one image, the user can capture multiple images with some overlap and the graphics system will match them up to form a "mosaic" image that can then be mapped to a geometric model.

In both the consumer and merchant images, the image provider might include cues to assist the graphics system in mapping the two-dimensional object onto the three-dimensional model. For example, the user might have an object in the scene that is a rectangular prism (such as a box, dresser, refrigerator, etc) and indicate the bounds of the rectangular prism on the two-dimensional image. The graphics system can handle shapes besides rectangular prisms, such as spheres, flat rectangles, arches, boolean combinations of simple shapes, etc., limited only by the shapes represented in a shape library that forms part of the graphics system. In a typical user interface, the user selects a shape while viewing an image and then moves the shape around to approximately coincide with an object in the image.

Because the images are mapped to a geometric model, the images of the scene and the objects to be inserted do not need to be taken from the same camera position. For example, a consumer might capture an image of a room from an angle, standing at the edge of the room, but a merchant might have captured an image of a rug they are offering for sale with their camera directly over the rug. As part of the processing performed by the graphics system, it determines camera parameters, such as

camera position in the geometric model, camera rotation, focal length, center of view, etc. Those parameters might already be available if the image capturing device is sophisticated or the camera is always held in a known position, but such parameters are usually not available and the graphics system will generate them from the images and
5 constraints.

The graphics system could be a localized system or a client-server system. For example, a server connected to clients over the Internet might be used to create an electronic commerce system in connection with one or more Web sites. Merchants could provide catalogs of goods to the server and the consumer could provide an image of a
10 scene to the server. The server could then return to the consumer an image of how the product would look in the scene. Since the images are mapped into a three-dimensional geometric model, the combination of the objects and the scene appear more realistically combined, even when taken with different camera parameters, than if the image of the object were just distorted and overlaid into an area of the image of the scene.

15 In variations of the basic systems, complex interactive objects can be provided for combination with a scene. For example, if the merchant provides multiple images of an object, the consumer can place the object in a scene at any angle. An object such as a chest of drawers might include the ability to open a drawer and view the effect. Additional, non-image information, such as a product description, pricing, etc., might also
20 be included with a complex object.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a high-level block diagram of a media processing engine residing on a network in a client-server configuration.

25 Fig. 2 is a detailed block diagram of the media processing engine with inputs and outputs to a network or otherwise.

Fig. 3(a) is a wedge structure; Fig. 3(b) is a box structure; Fig. 3(c) is another box structure.

Fig. 4(a) shows a cylinder structure; Fig. 4(b) shows a sphere structure; Fig. 4(c) shows a two box structures constrained to each other by equating point elements

30 Fig. 5(a) shows examples of boolean union, merge, intersection, and difference; Fig. 5(b) shows several three dimensional geometric structures and associated geometric elements and two dimensional features corresponding to a projection of the 3D elements into 2D.

Fig. 6(a) is an image of an object; Fig. 6(b) is the image of the object with annotations added to identify individual edge and point features of the object shown in the image.

Fig. 7 is the same image of the object with annotations added to identify
5 connected structure edge and point features of the object shown in the image.

Fig. 8(a) shows a 3D construction with the image of Fig. 6(a) with an unsolved box structure in its default initial position and an unsolved camera model; Fig. 8(b) shows a scene graph containing the box structure; Fig. 8(c) is the scene graph with a sphere structure added; Fig. 8(d) is the same scene graph with yet another structure added.

10 Fig. 9(a) is a 3D object construction containing two box structure and one sphere structure and corresponding to the scene graph of Fig. 8(d); Fig. 9(b) is the scene graph of Fig. 8(d) with an additional cylinder structure added.

Fig. 10(a) shows the relationship between a line in 3-space, a camera system in the same space, and the projection of that line into the imaging plane of the camera; Fig. 10(a) shows the construction of an error function quantifying the error
15 between a line segment annotated into the imaging plane of the camera and the projection of the 3D line through the camera and into the imaging plane

Fig. 11(a) shows another view of the 3D construction of Fig. 8(a). Fig. 11(b) shows the back projection of the 3D box into the image for the construction of Fig. 11(b) shows the back projection of the 3D box into the image for the construction of Fig. 8(a) and unsolved parameters; Fig. 11(c) shows a view of the construction of Fig. 8(a) with camera and box parameters recovered; Fig. 11(d) shows the back projection of the 3D box into the image for the construction of Fig. 8(a) and solved camera and geometry parameters.
20

Fig. 12(a) shows a sphere structure constrained to the top of a box structure pertaining to the construction of Fig. 9(a); Fig. 12(b) shows the same
25 construction with a boolean merge operation applied between the box and sphere structures; Fig. 12(c) shows construction of Fig. 12(b) with a box structure added; Fig. 12(d) shows the construction of Fig. 12(c) with a boolean difference operation applied between the two box structures; Fig. 12(e) shows the construction of Fig. 12(d) with a cylinder structure added; Fig. 12(f) shows the construction of Fig. 12(e) with a boolean
30 merge applied between the cylinder structure and the second box structure.

Fig. 13(a) shows a rectangular straight pipe extruded solid from a rectangle extrusion profile and linear extrusion path; Fig. 13(b) shows a curved profile extruded

solid tube from a curved profile and curved extrusion path; Fig. 13(c) shows a revolved solid generated from a curved profile and revolution axis.

Fig. 14 is a flow diagram showing the process for constructing 3D objects as assemblages of structures.

5 Fig. 15 is a flow diagram showing visibility processing on geometric models to determine which subfacets of the model each associated camera sees.

Fig. 16 is a flow diagram showing how visibility between cameras and geometry is resolved to reapply imagery back onto geometry.

10 Fig. 17(a) is a diagram of a Phantom Cursor graphical user interface mechanism; Fig. 17(b) is a diagram of the default 3-space construction created upon initialization of a phantom cursor.

Fig. 18(a) is an image of a room scene; Fig. 18(b) is the image of the room scene with a default quadrilateral phantom cursor graphic in its initial "floating" position; Fig. 18(c) shows the image of the room scene with the phantom cursor graphic modified by the user; Fig. 18(d) shows the phantom cursor image annotation overlay from Fig. 18(c); Fig. 18(e) shows the 3-space construction for the current phantom cursor example.

Fig. 19 is a flow diagram outlining the phantom cursor process.

Fig. 20 is a flow diagram outlining an image mosaic process leveraging the phantom cursor process

20 Fig. 21 shows three images of a room scene used as example input to the system mosaic processing method

Fig. 22 shows the three images with annotations applied as part of the mosaic processing

25 Fig. 23 shows the 3-space construction corresponding to the mosaic processing of the images of Fig. 22.

Fig. 24(a) shows a detailed diagram of a quadrilateral phantom cursor structure; Fig. 24(b) gives the parameterization of the vertices of a quadrilateral phantom cursor; Fig. 24(c) is a correspondence table that maps the relationship between 2D edge features and 3D elements of a quad phantom cursor.

30 Fig. 25 is an image created by mosaic of the three images of Fig. 21.

Fig. 26 is a flow diagram of an image collage process that leverages the phantom cursor process.

Fig. 27 is an image of a room scene with annotations added for collage processing.

Fig. 28(a) is an image of a rug product to be used for the collage processing; Fig. 28(b) is an image of a picture product to be used for the collage processing.

Fig. 29(a) shows the 3-space construction corresponding to the collage processing of the image of Fig. 27; Fig. 29(b) is the scene graph corresponding to the collage construction of Fig. 29(a).

Fig. 30 is an image that is the collage composition of the image of Fig. 27 with the product images of Fig. 28(a) and Fig. 28(b).

Fig. 31 shows an image of a room scene and an image of a television object to be composed with the scene image through collage processing.

Fig. 32 shows an image of the room scene after composition with the image of the television, as well as a generated alpha image that will correct undesired hidden surface regions.

Fig. 33 shows a final image of the collage construction of Fig. 32 after application of the alpha image.

Fig. 34 is a flow diagram outlining the process of creating a 3D scene model from one or more images and leveraging the phantom cursor.

Fig. 35 is an image of a room interior with annotations added for construction of a 3D model of the room based on the process outlined in Fig. 34.

Fig. 36 is a 3D model of the room depicted in Fig. 35.

Fig. 37 is a scene graph corresponding to the 3D model of Fig. 36.

Fig. 38 is an example of a 3D solid model constructed with functional parametric components.

Fig. 39 is a flow diagram showing how to integrate constructed object and scene models with various interaction and scaling options.

Fig. 40(a) is an image of a room scene with an annotation added to the depicted floor" representing the anchor point for an object to be inserted; Fig. 40(b) is the image with the rug object of Fig. 28(a) inserted at the anchor point on the floor.

Fig. 41(a) is the image with the rug object moved along the floor, away from the initial from the original anchor point; Fig. 41(b) is the same image with the rug moved to some other location on the floor.

Fig. 42(a) shows the scene graph of the scene construction for the scene of image of Fig. 40(a) prior to insertion of the rug object; Fig. 42(b) shows the construction

scene graph after the insertion of the rug object; Fig. 42(c) shows the constructed scene model with the inserted product model.

Fig. 43 shows the 3-space construction for a "force-fit" model integration procedure.

5 Fig. 44(a) is an image of a brown wooden CD cabinet; Fig. 44(b) is an image of a cubical pine storage box.

Fig. 45(a) is an image of a dark brown wood cabinet; Fig. 45(b) is an image of a cubical pine storage box.

10 Fig. 46 shows four images of a room scene generated by the construction of a 3D model of the room in Fig. 35, insertion of constructed 3D models of the products depicted in Fig. 44 and Fig. 45, and user-interactive navigation of the scene and movement of the product models within the scene.

Fig. 47 shows a 3D graphical product information display that "pops-up" provide information about a product.

15 Fig. 48 shows the room scene of Fig. 46 with both 2D and 3D product information displays active.

Fig. 49 is a diagram of multiple instances of the media processing engine operating over a network in client-server configuration.

20 Fig. 50 is a diagram of multiple instances of the media processing engine operating over a network in client-server configuration and operating as an electronic commerce merchandising system.

DESCRIPTION OF THE SPECIFIC EMBODIMENTS

25 A photogrammetric processing engine placed between the user and the solid modeling engine transforms the conventional "hand-eye" coordinated modeling interface to one driven by user-interaction with the input photographs. Photogrammetry is the art, science, and technology of obtaining reliable information about physical objects and the environment through processes of recording, measuring, and interpreting photographic images and patterns of electromagnetic radiant energy and other phenomena.

30 The user paradigm becomes one of *molding* and *sculpting* directly from imagery. Unlike conventional solid modeling systems, which require the user to manually size and place modeling geometry, the system automatically sizes and positions

(parameterizes) geometric entities, thus "fitting" 3D model entities to with 2D image features.

The system also automatically determines 3D parametric camera models for each photograph of the scene (e.g. location, pose, focal length, center-of-projection).

5 Having derived geometry and camera models, the system automatically produces a visual reconstruction and rendering of the scene through re-projection of the input imagery onto derived geometry.

Many types of planar and volumetric 2D image and 3D model constructions, compositions, and visualizations are realized. Methods for 2D image
10 mosaics and collages, 3D object and scene constructions, and compositions of these are disclosed. With the underlying image-based user paradigm, these methods are highly intuitive and enable a novice audience.

A network-based client-server system leveraging the solid modeling system is disclosed. This system is suited for a wide range of applications, from
15 professional CAD development and collaboration to Internet e-commerce activities.

The Internet is rapidly becoming a dominant medium for commerce. One area enjoying rapid growth is that of online shopping. While the Internet offers unprecedented convenience to consumers searching and researching products, there exist barriers to consumer willingness or ability to purchase certain products online. High
20 among these barriers is a shopper's desire to physically see or try out a product ahead of time.

To reduce such barriers, great effort is underway to deliver richer digital content to online product catalogs. At present, one solution is the creation and addition of interactive photorealistic 3D product models. The basic idea is to bring "virtual
25 showroom" experiences to online shopping.

While this capability is useful for products such as watches and tennis shoes, it is limited for items that need to be evaluated within the customer's application context. In shopping for kitchen cabinets, a consumer is most interested in how they would look in their home, not on a web page.

30 Disclosed is an e-commerce system allows online shoppers to "take home" products from online catalogs and try them out as an integral part of their online shopping experience. In one embodiment, as a client-server system, a merchant serves a client application enabling end-users to construct 3D representations of their environments from their own digital photography. With a target scene constructed, a server node serves

functional models of products that are readily composed with the end-user environments and allow the end-user to understand how they look, fit, and function.

Media Processing Engine (MPE)

Photogrammetric Media Processing Engine (MPE) 11 is shown in Fig. 1.

5 A more detailed diagram is shown as Fig. 2. The main functional components of MPE 11 are Graphical User Interface (GUI) 12, Photogrammetric Modeling Engine (PE) 13, Scene Graph and Ancillary Data Structures (SG) 14, Built-in 3D Parametric Object and Scene Geometry Library (BL) 18, Solids and Surfaces Geometry Engine (GE) 15, Visual Reconstruction Engine (VE) 16, and Rendering Engine (RE) 17.

10 Digital data and program transmission network 10 is a source of data and program input and output of the system and is an integral component and backbone of the client-server data processing model. In its current embodiment, the network is the Internet. However, the system is not limited to any particular physical data transmission network and data transmission protocol.

15 All data input, output, and process control is directed by user-interactive input 25 through Graphical User Interface 12. The disclosed invention system and methods are not dependent on a particular design and implementation of 12.

The system imports and exports 2D digital images as a fundamental data type. User digital images 24 are those acquired or obtained by the user and supplied to
20 the system or the network. Examples of user images are those acquired from acquisition devices such as a digital cameras and scanners or transferred from mediums such as CDROM. User digital images 24 are imported into the system or uploaded to network 10. Network digital images 21 are digital images downloaded from network 10. User digital images might also be downloaded as network images 21. As an example, user
25 images are processed by a third and delivered over the Internet.

The system imports and exports 3D geometric models as a fundamental data type. Geometric models are typically imported and exported with sets of 2D image texture maps assigned to the models. User 3D geometric models 23 are those acquired or obtained by the user and supplied to the system or the network. Examples of such models
30 are those acquired from acquisition devices such as scanner devices or transferred from mediums such as CDROM. User 3D models are imported into the system or uploaded to network 10. Network 3D models 20 are models downloaded from network 10.

Ancillary data input 22 imports general and information from network 10. For example, for images 21 and models 20, ancillary data 22 might specify size, color, price, and availability parameters. The user may also supply ancillary data, such as certain known dimensions of an object or feature, through user interactive input 25.

5 The system imports and exports project databases providing a convenient mechanism for project saving, restoration, and work collaboration. Project databases include system generated scene graph and other data structures and accompanying data. Data 22 imports project databases and all general data associated with incoming 2D and 3D media from network 10. Data input 28 imports project databases from storage
10 medium such as system memory or disk. Output 26 exports project databases to storage mediums such as system memory or disk. Output 27 exports project databases to network 10.

 System output 26 consists of 2D images, generated 2D images and image compositions, 3D models, 3D models and 3D texture-mapped object and scene
15 compositions generated from 2D images, and compositions of all of these. Output 26 is directly viewed on a computer display device, stored on digital storage mediums such as computer hard disk. System output 27 sends system output 26 to network 10.

Scene graphs are used to store geometric, topological, and visual construction information. A scene graph conveniently and efficiently encodes a
20 hierarchical organization of the components that comprise the scene. The scene graph and ancillary data structures are stored in data structures unit 14.

 A scene graph is made up of *nodes* that represent geometric components drawn, properties of the components, hierarchical groupings of nodes, and other information such as cameras and visual reconstruction information. Nodes are connected
25 by *links* in a parent-child hierarchy. The scene graph is processed or traversed from node to node by following a prescribed path of links. Nodes and links contain parameters. Nodes contain the parameters associated with the geometric structures they specify. Links contain the spatial relationships (e.g. rotation, translation, scale) between the geometric primitives (structures) of the interconnected nodes. A *tree* structure is an
30 example of one of the most common types of graph structures. Another form of scene graph is a *directed acyclic graph* (DAG). The specific form of the scene graph is not essential to the invention as described here. Fig. 4(d) shows a scene graph 55 with two nodes and one link.

For media construction, photogrammetric modeling engine 13 and visual reconstruction engine 16 read from and write to the scene graph data structure. For media presentation, rendering engine 17 reads the scene graph data structure and composes a visual representation.

5 The Photogrammetric Modeling Engine 13 is highly-automated photogrammetry and constraints based modeling system that embodies a process for recovering parametric 3D geometric structure and camera models from 2D images. Under the direction of user interactive input 25, the system produces parametric and non-parametric polyhedral and solid (volumetric) models of image compositions and 3D
10 models of objects and scenes depicted in supplied 2D digital imagery. Modeling Engine 13 recovers parametric camera models for each input image of a construction project.

Geometric constructions generated by the system are hierarchical and non-hierarchical assemblages of geometric components called "structures". Structures are parameterized geometric primitives, such as points, lines, line segments, planes, cubes,
15 squares, rectangles, boxes, cylinders, cones, frustums, wedges, surfaces of revolution, and extrusions.

A structure contains a set of parameters describing its size and shape. The coordinates of each vertex of a structure are expressed as a linear combination of these parameters, relative to the structure's internal coordinate frame. The spatial extent of a
20 structure is specified as a bounding volume. In Fig. 3(a), half-wedge structure 49 is defined by shape parameters *wed_width*, *wed_height*, and *wed_depth*. A vertex VE1 is expressed as $(-wed_width, wed_depth, 0)$. The spatial extent of structure 49 is defined by rectangular bounding volume 54. In Fig. 4(a), cylinder structure 50 is described by three parameters *cyl-radiusA*, *cyl-radiusB*, and *cyl_length*. The first two parameters
25 control diameter and the third controls length. When *cyl-radiusA* and *cyl-radiusB* are equal, the cylinder is circular; otherwise the cylinder is elliptical. The extent of the cylinder is given by bounding box 58. The cylinder might also contain radius parameters at the "other end" of the cylinder, thus defining tapered cylinder profiles. In Fig. 4(b), sphere structure 51 is described by radius parameter *sphere-radius* and bounding box 59.

30 Structures are also generated, as in the case of extruded and revolved solids. Shown in Fig. 13(a) is an extruded rectangular box structure XX. It is generated by translating rectangular profile element X10 along linear extrusion path element P10. Fig. 13(b) shows an extruded object XX with a more complex curved profile element X20

and curved path element **P20**. Fig. 13(c) shows a solid structure **XX** generated by revolving profile element **X30** around sweep axis element **P30**.

The system embeds a library of built-in structures **18**, including, but not limited to, fundamental geometric structures typically associated with conventional solid modeling systems. Library **18** is fully extensible and the number and types of structures supported may be tailored to suit the application software used. New classes of structures are pre-programmed into built-in library **18**, imported as user input **23**, or downloaded as network input **20**.

Geometric structures are comprised of *elements*. An element is a component of a structure or higher-level construct or possibly a 3D structure itself, as in the case of a point. It represents a 3D structure part or shape that can be transformed and projected into the planes of related 2D input images. Examples of elements include points, lines, line segments, planar polygons, circles, and curves.

In Fig. 3, structures **49**, **52**, and **53** comprise *edge* and *point* type elements. Point elements are structure vertices and edge elements are line segments forming edges between structure vertices. In Fig. 3(b), "box" structure **52** has eight vertex elements, **VE40** through **VE47**. Connecting these vertex elements are 12 edge elements. For example, edge element **EE24** is the line segment formed between vertices **VE42** and **VE46**.

The number and type of elements supported by modeling engine **13** is fully extensible. The system does not limit the vocabulary of geometric elements supported. Any component of a geometric structure or higher-level construct that can be projected and identified in the imaging plane of a camera (plane of an image) may be defined as an element. Fig. 5(b) shows several examples of 3D structures and component element types. Point **64** is itself a structure and an element. Edge structure **66** is an edge element comprised of two vertex (point) elements and a connecting line segment. Box structure **68** contains individual point elements and edge elements. Cylinder structures **70** and **74**, and sphere structure **72** are comprised of point elements, edge segment elements, circle, and ellipse elements. For generated structures, such as the extruded and revolved solids of Fig. 13, elements include defining profiles and paths.

The relationships between component structures in the hierarchy of a model assembly are represented by parametric *operators*, which encode spatial and geometric relationships between structures. In the present embodiment, *spatial operators* are the affine geometric transformations of rotation *R*, translation *T*, and scale *S*. In

general, operators may also specify non-affine spatial transformations. *Geometric operators* determine the topology of the overall model assembly. Fig. 5(a) shows the *boolean* operators union 60, merge 61, intersection 62, and difference 63. Geometric operators also include, but are not limited to, blending, sweeping, imprinting, covering, lofting, skinning, offsetting, slicing, stitching, sectioning, and fitting. Geometric operators are processed by geometry engine 15.

3D geometric models are related to 2D images through annotations marked on images called *features*. A feature represents the projection of a 3D model element into the plane of projection of the camera attached to the image. The parameterized camera model attached to the image specifies the projective transformation.

Fig. 5(b) illustrates several projective relationships between 3D structure elements and 2D image features. Point, line segment, and circle elements in 3-space project into point, line segment, and ellipse features in 2-space, respectively. 3D point structure 64 projects into 2D point feature 65. 3D edge structure 66 projects into 2D edge feature 67. 3D point and edge segment elements of box structure 68 and cylinder structures 70 and 74 project into point and edge features 69. 3D circle elements of cylinder 70 and ellipsoid elements of cylinder 74 project into 2D ellipse features 71. 3D circle features of sphere 72 project into 2D circle features 73.

The modeling engine modeling process entails the marking of features in one or more input images and the establishment of correspondence between these 2D features and geometric elements of a 3D construction. In the present embodiment, the user places features in images through user-interactive input 25 and interface 12. An optional gradient-based technique aligns marked edges to image pixel features with sub-pixel accuracy.

As an example, image I100 of Fig. 6 is annotated with edge and point features, resulting in image I101. In image I101, edge features F20 through F31 mark selected edge regions. Geometrically, each 2D edge feature is composed of two endpoint vertices and a connecting line segment. For example, edge feature EF24 contains endpoint feature vertices VF10 and VF11. The endpoints of marked edge features need not align with depicted endpoints of a selected edge in the image; the placed line segment need only align with the associated edge in the image. In image I101, in addition to edge features, point features VF50 and VF60 mark individual point feature positions in the image.

Correspondence establishes a relationship between 3D elements of structures in global position and 2D image features. A single correspondence is a feature-element pair. A geometric element can have multiple image correspondences.

Correspondence types define valid feature-element pairs that quantify the
5 degree of geometrical coincidence of the projected view of a geometric element and a 2D image feature, relative to the camera associated with the image. Valid correspondence types are defined for each geometric element or higher-level construct. Example feature-element types include point-point, point-edge, and edge-point pairs. The system is fully extensible and not limited to a specific vocabulary of correspondence types.

10 The degree to which an annotated 2D image feature and a projected geometric element align is expressed in terms of a *correspondence error*. The manner by which the correspondence error is measured depends on the correspondence type. A *correspondence error metric* is defined for each valid correspondence type and quantifies the degree of geometrical coincidence of the projected view of the element and the
15 feature.

Correspondences are established implicitly or explicitly. In the former case, features are placed in images and 3D structure elements are explicitly associated with them. In the latter case, images are annotated with features that directly (implicitly) correspond to structures and their elements. Correspondences may also be implicitly
20 established by application program design.

As an example of explicit correspondence, edge correspondences are established between "box" structure 52 of Fig. 3(b) and image I100 of Fig. 6.

Through user-interactive input 25 and interface 12, individual 2D edge features EF20, EF21, EF22, EF23, and EF24 are annotated, as shown in image I101.
25 These features are then explicitly assigned to 3D structure 52 edge elements EE20, EE21, EE22, EE23, and EE24, respectively. In the present implementation, feature-to-element pairings are established through a "point-and-click" user interactive interface.

With implicit assignment, structures are associated with images directly as feature annotations. For the present example, image I101 is annotated with structure 52
30 by placing 2D vertex features into the image that directly correspond to 3D vertex elements VE40 through VE47, as shown in Fig. 7 image I103. In doing so, edge elements adjoining the vertices implicitly correspond to (and serve as) edge features in the image. In the present implementation, as structure vertices are placed,

interconnecting edges “rubber-band” in place, thus presenting the structure as a “pliable” 2D annotation object.

Constraints are values set for parameters of a construction. By reducing the number of unknown parameters of a construction, the computational load of parameters to be recovered by modeling unit 13 is reduced. Constraints may be placed on any values of a construction parameter-space, including structure shape parameters, spatial and geometric structure operators, and intrinsic and extrinsic camera parameters. Constraints on the parameter-space of a 3D model and camera construction may be defined by the application or explicitly specified by user-interactive input 25 through 12.

Structures may have their individual shape parameters constrained to specific fixed values. For example, setting structure 52 parameters *base_width*, *base_depth*, and *base_height* to x units each establishes a cube structure of $2x$ units in each dimension. In the present embodiment, the system treats parameters symbolically, so parameters are conveniently shared between structures. Equality is a common type of constraint. For example, if Fig. 3 structure 53 parameter *door_depth* is set equal to structure 52 parameter *base_depth*, the depth of both structures remain the same, even under varying values of *base_depth*.

Constraints on spatial operator parameters fix the placement of structures. In Fig. 9(a), structures 51, 52 and 53 are spatially constrained by the rotation R , translation T , and scale S operators linking them. In this example, with the given default bounding volumes, R is set to null (no rotation in any axis) between 51 and 52 and between 52 and 53. Between 52 and 53, translation T is set such that the midpoints of structures 52 and 53 align in the x -axis and z -axis and the minimum bounding extents of structures 52 and 53 are coincident in the y -axis. Between structures 51 and 52, translation T is set such that the midpoints of structures 52 and 53 align in the x -axis and z -axis. Scale S is set to unity for all structures.

As another example, a user interactively selects and equates structure vertex elements. In Fig. 4(c), structure 53 is attached to the top of structure 52 by the user selecting and equating vertex elements VE44 and VE13, VE47 and VE16, and VE46 and VE15. This constraint specification sets the spatial translation T and rotation R between the structures to zero while also equating their width and depth shape parameters.

Cameras

Associated with each input image is a 3-space *camera* system that models the imaging process between structures in 3-space and corresponding features in 2-space.

Camera models are parametric and include variable parameters describing external pose and internal settings. For pose, three parameters C_x , C_y , and C_z describe 3-space position and three parameters R_x , R_y , and R_z describe angular viewing direction. For internal calibration, parameters include focal length f and center-of-projection parameters cop_x and cop_y . A camera's pose and internal projection parameterization is composed into a homogenous 4x4 matrix. The composition of the intrinsic projection transformation and extrinsic pose transformations specify the mapping of an arbitrary 3D point in the global 3D coordinate frame into the camera's image plane.

Geometry and Camera Reconstruction Processing

In contrast to a conventional modeling system which requires the user to manually size and place modeling geometry, the modeling engine 13 automatically sizes and positions (parameterizes) geometric structures. Modeling engine 13 also determines 3D camera models (location, pose, focal length, center-of-projection). Camera model derivation is an intimate component of the photogrammetric process and is central to subsequent visual scene and object reconstruction.

Modeling engine 13 recovers all unknown unconstrained variables of a construction parameter space to form a reconstruction of depicted objects or scenes and the cameras that image them. The solution of the geometry and camera parameterization aligns 3D model elements with corresponding 2D image features and allows recovered camera system to accurately project (re-project) their imagery onto geometric representations.

Modeling engine 13 solves for the variable parameters by minimizing the aggregate correspondence error (sum of all correspondence errors). This is a nonlinear multivariate function referred to as the *objective function* O . Minimizing the objective function requires nonlinear minimization. Defined constraints eliminate variables and thereby reduce the dimensionality of the unconstrained nonlinear minimization process. In addition, it makes use of invariants and linearities to progressively minimize the function.

Fig. 10(a) illustrates an *edge-to-edge* correspondence type and implementation of the present embodiment. Line element $E70$ of a 3D model projects onto image plane 71 of camera $C10$. The 3-space line $E70$ is defined by a pair of vectors $\langle v, d \rangle$ where v represents the direction of the line and d represents a point on the line.

The world coordinates $P_w(X)$ of a structure vertex $P_s(X)$ is $P_s(X) = s_1(X) \dots s_n(X)P_s(X)$, where X represents the vector of all structure parameters and $S_1(X) \dots S_n(X)$

represent the spatial operators linking structures. The world orientation $v_w(X)$ of a particular line segment $v(X)$ is given as $v_w(X) = S_1(X) \dots S_n(X) v(X)$.

The position of camera C10 with respect to world coordinates is expressed in terms of a rotation matrix R_j and a translation vector T_j . The normal vector m is
 5 computed as $m = R_j(v(X)(d - T_j))$.

The projection of line element E70 onto image plane 71 is projected edge segment B74. Edge segment B74 is the intersection of plane 73 defined by m with image plane 71, located at $z = -f$ where f is the focal length of the camera. The computed image edge segment B74 is defined by the equation $m_x x + m_y y - m_z f = 0$.

10 An annotated image edge feature F75 is delimited by image feature vertices VF20 and VF21, with image coordinates (x_1, y_1) and (x_2, y_2) , respectively, and is denoted as $\{(x_1, y_1), (x_2, y_2)\}$.

The disparity (correspondence error) between a computed image edge B74 and an annotated image edge F75 is Err_i , for the i th correspondence of the model
 15 construction. Fig. 10(b) shows how the error between edges B74 and F75 is calculated. Points on the annotated edge segment F75 are parameterized by a single scalar variable $s \in [0, l]$ where l is the length of the edge. A function, $h(s)$, returns the shortest distance from a point on the segment, $P(s)$, to computed edge segment 74.

With these definitions, the total error between marked edge segment F75
 20 and computed edge segment B74 is calculated as

$$Err_i = \int_0^l h^2(s) ds = \frac{1}{3} (h_1^2 \mid h_1 h_2 \mid h_2^2) = m^T (A^T B \ A) m$$

$$m = (m_x, m_y, m_z)^T$$

$$A = \begin{pmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{pmatrix}$$

$$B = \frac{l}{3(m_x^2 + m_y^2)} \begin{pmatrix} 1 & 0.5 \\ 0.5 & 1 \end{pmatrix}$$

The reconstruction minimizes the objective function O that sums the
 25 disparity between the projected edge elements of the model and the marked edge features in the images. The objective function $O = \sum Err_i$ is the sum of the error terms resulting from each correspondence i . O is minimized using a variant of the Newton-Raphson

method, which involves calculating the gradient and Hessian of O with respect to the variable parameters of the camera and the model.

In the present embodiment, symbolic expressions for m are constructed in terms of the unknown model parameters. The minimization differentiates these expressions symbolically to evaluate the gradient and Hessian after each iteration. The reconstruction algorithm optimizes over the parameters of the model and the camera positions to make the model conform to the observed edges in the images.

Modeling engine 13 writes to, and reads from, scene graph unit 14. This data exchange includes 2D images 30, parameterized geometric structures 31, parameterized operators and constraints 32, parameterized camera models 33, and ancillary data 34 which includes images features and correspondences.

Solids and Surfaces Geometry Engine (GE) 15 reads the scene graph and performs specified geometric operations on the construction. The resulting fundamental and complex geometric structures and models are sent back to scene graph unit 14 via 39 or are stored in built-in library 18 via 35 and augment the library. The latter generates structures beyond those pre-existing in 18. The output 40 of geometry engine 15 is also sent to visual reconstruction processor 16.

GE 15 supplies operations on and between all structure classes. This includes solid structures operating on surfaces structures and vice versa. Operations on and between geometric structures include, but are not limited to, *booleans*, *extrusions*, *sweeps*, *revolutions*, *lofts*, *blending*, *shelling*, and *local manipulation* and *deformation*. For example, boolean operations between a given set of shapes allow the creation of an infinite number of simple and complex shapes.

Fig. 5 shows example boolean operations union 60, merge 61, intersection 62, and difference 63 performed by GE 15. Geometric operators also include, but are not limited to, blending, sweeping, imprinting, covering, lofting, skinning, offsetting, slicing, stitching, sectioning, and fitting. Fig. 13(a) and Fig. 13(b) show examples of extrusion processing by GE 15. Fig. 13(c) shows an example of surface-of-revolution processing by GE 15.

The Visual Reconstruction Engine 16 automatically applies 2D input imagery onto 3D geometric models using recovered 3D camera models. The application of the input imagery onto the output geometry involves a re-sampling of the input imagery, a process commonly called texture-mapping. Conventional texture-mapping systems typically require users to manually and explicitly specify texture-to-geometry

mappings. Such conventional approaches are labor-intensive and yield inaccurate results. Visual reconstruction engine 16 automatically determines the texture mapping strategy for visually reconstructing scenes and objects on a facet-by-facet basis. This includes determination of which texture map(s) to apply to each facet of the scene geometry, calculation of the texture coordinate parameterization, and texture rectification (as
5 required). Camera-image assignments are made to constructed geometry based on the results of visibility tests and established image quality criteria.

The input to 16 is a database containing 3D object and scene geometry models, camera models 36, imagery 37 associated with each camera model, and
10 geometric object and scene models 38 and 40.

Output 42 of 16 is a graphical database that is ready for processing by rendering engine 17 or export for further processing by another graphical database rendering apparatus or storage. The invention is not limited to any particular geometry, camera, or texture data format or rendering procedure. The specific output of
15 reconstruction engine 16 output 42 is a function of the processing modality of media processing engine 11 and the media type produced.

For processing of 3D texture-mapped geometric object and scenes from one or more 2D images, visual reconstruction processor 16 produces a graphical database that includes camera maps, texture maps and coordinates, camera models, and 3D object
20 and scene geometry. A *camera map* is an assignment of cameras to scene geometry. For each triangular facet of model geometry seen by at least one camera, a camera map produced by 16 designates a single "best" camera or group of cameras whose imagery is available and appropriate to texture map the triangle.

Hybrid Camera-Geometry Visibility Processing

25 Visibility processing is required to determine, for each (camera, image) pair in a given 3D scene, which facets of scene geometry (in whole or in part), are visible from the viewpoint of the camera. For visible/hidden surface determination, the system considers back-facing surfaces, surface visibility with respect to the extent of each camera's viewing frustum, and surface visibility within a camera's view frustum and in
30 consideration of occlusions (partial and full) amongst the various surfaces. The latter two categories are referred to here as *window visibility* and *occlusion visibility*, respectively.

Window visibility is resolved by intersecting surfaces with a camera's viewing frustum, subdividing surfaces based on intersections, and selecting portions

contained within the viewing frustum. Occlusion visibility is resolved by computing the intersections of object surfaces with each other. Then for each set of intersections, it is determined which surface is closer to the viewer (camera) and thus visible.

Visual reconstruction engine 16 presents a hybrid visibility processing approach, invoking both *object-space* and *image-space* visibility computation. Image-space and object-space visibility processing algorithms differ in the precision with which they compute the visible surfaces. Image space algorithms determine visible surfaces by examining surfaces at the pixel level, post-projection in to the imaging plane of the viewer. Object space algorithms directly compare surfaces in the defined space. Object space calculations are employed for computing the intersections of surfaces in the defined global 3D coordinate system of the geometry. Image-space computations process geometry visibility in the projected screen space of each camera. A hybrid approach is preferred, since it can be fully implemented in software or make use of commonly available computer graphics hardware. It allows the system to run on a host computer systems with or without 3D graphics capabilities (software or hardware). For systems with 3D graphics capabilities, including hardware acceleration, the application can effectively leverage available resources.

Preferably, all geometry is processed as triangles, but any n-sided polygons or other representations could be used.

The visual reconstruction process is executed in two stages. The first stage of the visual reconstruction process is a determination of the visible triangles relative to each scene camera. This is a multiple step process carried out for each camera. Fig. 15 shows a flow diagram of the process.

At step ST70, all triangles are initialized as being visible and surface normals are computed for each. Triangles are backface filtered by taking the *dot product* between the triangle normal n and the camera viewing direction v determines if the triangle is back or front facing to the camera. If back-facing, a triangle is marked as not visible.

At step ST71, each triangle not filtered out at step ST70 is clipped against the camera frustums. An object-space clipping algorithm checks each triangle in three stages: trivial accept, trivial reject, and clip. If a triangle is trivially accepted, then it remains marked visible. If a triangle is trivially rejected (culled out of the cameras view), then it is marked not visible to the camera. Otherwise, the triangle is intersected (clipped) against the camera frustum. The triangle is then triangulated (subdivided) with the new

intersection vertices. In the present implementation, Delaunay triangulation is employed. The resulting sub-triangles that are within the view frustum are marked as visible to the camera; those outside the frustum are marked as not visible.

At step ST72, occluded triangles (surfaces) are identified. An example of
5 an occluded triangle is one that is fully or partially obscured from a camera's viewpoint by another triangle or group of triangles. Triangles that are fully occluded are marked as not visible. Triangles that are not occluded at all remain marked visible. Otherwise, for each partially occluded triangle, a list of those triangles that occlude it is produced. At
10 step ST72, the system or the user selects image-space computation or object-space computation for resolution of hidden surfaces. If an object-space computation is selected, process flow proceeds to step ST73. Otherwise, process flow proceeds to step ST74.

At step ST73, an object-space algorithm computes analytic visibility in two stages. The first stage is a sort of the triangle database in 3-space. The second stage is a determination of the visible triangle fragments in a camera imaging screen.

15 3D Scene Visibility Tree

The system utilizes a 3D binary space partition (BSP) tree to accomplish a global visibility sort of the input database. The BSP tree sort recursively subdivides the object space and geometry with hyper-planes defined by the surface facets of the input. From any given arbitrary viewpoint, a subsequent traversal of the tree will deliver
20 triangles in a spatially correct "back-to-front" or "front-to-back" ordering.

The scene visibility tree is traversed in a front-to-back order. Each triangle encountered is ray-projected into the camera imaging plane and inserted in a 2D BSP referred to as 2D camera visibility map.

25 2D Camera Visibility Map

A camera visibility map depicts the visible geometry of the scene, as viewed by a camera and projected into its imaging plane (screen). In the event of inter-object occlusions, the visibility map resolves hidden surfaces, depicting resulting visible geometry fragments. A camera visibility map is constructed for each camera in the scene. The object-space camera visibility map is encoded as a 2D BSP tree. In two-dimensions,
30 a BSP tree partitions a camera screen. Edges of the input geometry projected onto the imaging plane define the lines partitioning the space.

The screen of the camera is partitioned into regions that are occupied with projected geometry (G-regions), and those unoccupied (U-regions). When a polygon (triangle) is inserted, it is and clipped to visited U-regions. In the process, the clipped

visible region of the polygon overlapping the U-region becomes a G-region. That is, it is removed from the visible region of the screen.

For a triangle, 3 edges become 3 line partitions. Each line recursively subdivides the camera screen into two new sub-planes.

5 G-regions and U-regions appear as leaf nodes in the tree. G-regions are tagged to identify their specific origin. Insertion of geometry stops when there are no U-region nodes (screen is full). Intersections of input geometry and previously inserted geometry (G-regions) detected. This determines, for a given triangle, which, if any other triangles obscure it. Fully occluded geometry is identified and tagged.

10 At step **ST74**, an image-space occluded surface algorithm is processed. The image-space algorithm may be implemented entirely in software or utilize 3D graphics hardware if available. The algorithm computes visibility by rasterizing triangles into a 3D graphics frame buffer and also has a z-buffer. Each triangle is rendered with a unique identification value. To determine which triangles are fully occluded, all triangles
15 are rendered into the frame buffer with z-buffer to resolve hidden surfaces. The frame buffer is subsequently scanned and the triangle identification numbers present in the buffer are recorded. Those triangles whose identification numbers do not appear in the frame buffer are deemed fully occluded.

 The determination of whether a given triangle is occluded, and if so, by
20 which triangles, is as follows. For each triangle, a mask is generated such that a scan of the previously rendered frame buffer will read only pixels contained within the given triangle. The frame buffer is scanned and the triangle is determined to be fully visible if the pixel values read back are only equal to the triangle ID value. If this is not the case, then the triangle is partially obscured, and the triangles which obscure it are identified by
25 the ID values found. Projected areas of triangles (in pixels) are also determined by rendering a triangle and counting the occurrences of its ID value in the frame buffer.

 At step **ST75**, each occluded triangle is intersected (clipped) with all those that occlude it. The triangle and intersections are Delaunay triangulated. Fully occluded sub-triangles are marked as not visible. Others are marked visible. The projective area of
30 each visible sub-triangle is calculated.

 The second stage of the visual reconstruction process is an assignment of a cameras to triangles for texture mapping. **Fig. 16** illustrates this process.

 For each triangle and for each camera which "sees" the triangle, the angle between triangle normal and camera view direction is calculated. In the present

embodiment, the camera presenting minimum view angle and maximum projective area is selected to map onto a given triangle.

Rendering Engine

Rendering Engine 17 is the visual rendering processor of media processing engine 11, producing all real-time and non-real-time visual output during media creation or playback. During interactive modeling and reconstruction processing with 11, 17 serves "in the loop" as the rendering engine for all graphical display. Rendering Engine 17 reads scene graph and ancillary data unit 14 and constructs visual output representations. Visual output 26 is suitable for direct display on a computer graphics display system or storage on a medium such as a computer hard disk. Rendering Engine 17 output 27 is sent to network 10.

Output 26 of 17 includes 2D images, 2D Image mosaic compositions, 2D image collage compositions, 3D texture-mapped object and scene compositions, and compositions of all of the above. The specific output depends on the processing modality of the system and the type of content produced.

The current and preferred embodiment of 17 is real-time *projective-texture* based apparatus and method for rendering a project scene graph on a host computer that supports projective texture mapping in a 3D graphics API such as OpenGL or Direct3D. In general, a real-time capability and use of these graphics API's are not required. In its present embodiment, 17 utilizes projective texture mapping [2] to texture map 3D geometric constructions directly from the original input images used to model the scene and the camera models recovered by the system. The rendering paradigm is one of treating the cameras in the scene as projectors, loaded with their images, and projecting these images back onto the recovered 3D geometric models. Since the 3D scene geometry and camera models were recovered directly from these images, such a projection (re-projection) process completes the loop in reconstructing the scene. The invention also does not require that rendering be executed using the projective texture mapping paradigm. Reconstruction processor 16 subsystem optionally outputs ortho-rectified texture maps and non-projective texture coordinates for rendering using non-affine (orthographic) texture mapping.

For efficient texture map management and overall rendering, the rendering engine 17 implements a tiling scheme for loading only those regions of interest of the input images required at any given stage of the rendering.

3D Object Construction

A process of constructing a parametric 3D solid object model from one or more 2D images depicting the object is disclosed. In the present example, object constructions are compositions of volumetric structure components. In general, modeling engine (PE) 13 and geometry engine (GE) 15 support an extensive and extensible library of structure components, ranging from individual point structures to complex parametric surface structures. A 3D construction process flow diagram is shown as Fig. 14.

The process is exemplified with the construction of the domed-arch object depicted in image I100 of Fig. 6. The arch object is constructed with structure components 50 and 51 of Fig. 4 and structure components 52 and 53 of Fig. 3. The resulting model construction 100 is shown as Fig. 12(f). Scene graph 375 of Fig. 9(b) depicts the construction hierarchy, with nodes N20, N21, N22, and N23 containing structures 52, 53, 51, and 50, respectively.

At step ST50 the user imports an object image 24 or downloads an object image 21. Ancillary data 22, such as accompanying parametric descriptors of objects depicted in imagery, is also downloaded at step ST50. Ancillary data might also be imported as data 24, for example in the case of digital acquisition devices that provide such information.

In the present example object image I100 of Fig. 6 is downloaded from network 10. A default 3D construction coordinate system is established with camera C100 belonging to image I100 assuming an arbitrary default 3-space pose and internal parameterization.

At step ST51 a model structure is selected and instantiated. In the present example, the user selects a "box" structure from built-in library 18 which is instantiated by the system as structure 52. Structure 52 serves as the base of the domed-arch object construction and contains three shape parameters *base_width*, *base_height*, and *base_depth*. By default, the first structure is spatially constrained to the origin of the 3D construction coordinate system. Fig. 8(a) shows the initial scene construction with structure 52 constrained to the origin of the 3-space coordinate system. The values of structure 52 shape parameters and camera C100 internal and external parameters are initialized to arbitrary default values. The system inserts "base" structure 52 as root node N20 in scene graph 375 of Fig. 8(b).

At step ST52, through user-interactive input 25 and interface 12, the user interactively places feature annotations in the current input image and establishes

correspondence between model structure elements and image features. In the present example, line segment edge features **EF20, EF21, EF22, EF23, EF24** are placed in image **I100**. These annotated features are shown in image **I101** of Fig. 6. This set of features is sufficient to identify the *x*, *y*, and *z* extents of the base object. Feature pairs

5 **EF20-EF21, EF22- EF23, and EF21-EF24** set *x*, *y*, and *z* dimensional extents, respectively. Annotated features **EF22** through **EF24** are corresponded by the user to geometry edge elements **EE20** through **EE24**, respectively. In the present example, this correspondence is done explicitly by the user through a simple point-and-click mechanism within **12**.

10 Alternately, the establishment of feature annotations and their correspondence to structure geometry is done directly and implicitly, as previously described. For the present example, in this modality, image **I100** is marked with structure **52** vertex elements **VE10, VE11, VE12, and VE13**.

The construction parameter space includes nine unknown parameters for

15 camera **C100** (six pose, one focal length, and two center-of-projection), three unknown shape parameters *base_width*, *base_height*, and *base_depth* for structure **52**, and nine spatial operator parameters (three each for rotation, translation and scale). For the default initialization of the first structure, the spatial operator parameters are fully constrained. To set a relative object scale, one or more shape parameters are set to arbitrary default

20 values by the system or user. To set an absolute object scale, one or more shape parameters are set to of known real dimensions by the system or user. Parameter values may be imported into the system as ancillary data **22** accompanying the import of an image **21**. In the present example, parameter *base_width* is set to 1.0 units to establish a relative scale. Intrinsic camera parameters may also be set to known calibration values by

25 the system or user.

At step **ST53**, photogrammetric modeling engine **13** solves the parameter space of all unknown geometry structure and camera parameters. In the present example, modeling engine **13** executes its reconstruction algorithms to recover nine parameters defining camera **C100** and two unknown and unconstrained shape parameters

30 *base_height* and *base_depth*. Fig. 11(a) shows the construction prior to recovery of shape and camera parameters. In Fig. 11(b), image **I104** depicts structure **52** base geometry back-projected into image **I100** with unrecovered shape parameters and from the unrecovered camera **C100**. In Fig. 11(c), camera and shape parameters are recovered. In

Fig. 11(d), image I105 shows structure 52 geometry back-projected into image I100 with recovered shape and camera parameters. The geometry now aligns with the image.

At step ST54 the system inquires as to whether geometry engine GE 15 is to evaluate geometric operators between nodes. If no, (or there is only one node, as is the case for the present example) the process proceeds to step ST56. Otherwise, the process proceeds to step ST55, where all unperformed operations are executed by GE 15. In the present example, the user elects to perform geometric operations after the addition of each new structure.

At step ST56 the system inquires as to whether additional structures are to be added to the present construction. If yes, process flow proceeds back to step ST51 with the selection and insertion of the next structure. Otherwise, process flow proceeds to step ST57.

At step ST57 the system inquires as to whether additional images are to be added to the project. If yes, process flow proceeds to step ST50 where a new image is loaded and process enables marking the new image and corresponding marked features of the image with existing or new structure elements. Otherwise, process flow proceeds to step ST58.

At step ST58, the scene graph is traversed and geometry engine 15 executes all unprocessed geometric operators. If in all geometric operators where already executes at step ST54, processing is complete.

In the present example, additional structures 51 and 53, and 50 are added, so process flow cycles back through step ST51 three times.

At step ST51, structure 51 is instanced to represent the dome of the object construction. The system inserts "dome" structure 52 as node N22 in scene graph 375 of Fig. 8(c). Spatial operator $S_{20}(X)$ in link L1 between scene graph nodes N20 and N21 of scene graph 375 encodes the spatial parameters between structures 52 and 51. Variable parameters of translation, rotation, and scale are explicitly constrained to position the "dome" component relative to the base component, as shown Fig. 9. Link L1 contains the geometric boolean merge operator 61 specifying that structure 51 will be combined with base structure 52.

To position the dome on top of base structure 52, the midpoint of the y bounding extent of structure 51 and the maximum y-extent of structure 52, are equated. To center it, the midpoints of the x and z bounding extents of the two structures are equated. As previously discussed, the system allows for many ways to specify

constraints. For example, vertex element VE30 at the center of sphere structure 50 could be directly equated to the midpoint of the top face of structure 52.

Constraints are also placed on structure 51 shape parameters. The sphere shape parameter *sphere_radius* is set equal the base structure size *cbase_depth*. To solve for the dome height *sphere_radius2*, point feature VF50 is marked in image I101 of Fig. 6(b) and is corresponded to vertex element VE31 of structure 51.

At step ST53 modeling engine 13 solves for the dome height parameter *sphere_radius2*. If previously solved parameters are not "locked", the engine will optionally resolve them.

At step ST55, the boolean merge operation between nodes N20 and N21 is executed by geometry engine 15. Fig. 12(a) shows the construction prior to the geometric operation. Fig. 12(b) shows the construction after to the geometric operation.

For the present example, the above process flow repeats twice, once for the addition of box structure 53 and once for the addition of cylinder structure 50.

Box structure 53 serves as the door opening of the arch assembly, as shown in Fig. 9(a). It is inserted as "door" node N22 in scene graph 375 of Fig. 9(b).

To position the door, spatial operator $S_{21}(X)$ in link L2 is set such that the minimum y-extents and midpoint x-extents of structures 53 and structure 52, are equated. Link L2 contains the boolean difference operator 63 specifying that structure 51 will be combined with base structure 52.

To constrain the depth of the door to that of its parent base, shape parameters *door_depth* and to *base_depth* are equated. As shown in image I101 of Fig. 6(b), edge features EF22, EF30, EF28, and EF29 are marked. These are corresponded to edge elements EE22, EE30, EE28, and EE29 in Fig. 9(a).

At step ST53 modeling engine 13 solves for the door width and height parameter *door_width* and *door_height*.

At step ST55, the boolean difference operation between nodes N20 and N22 is executed by geometry engine 15. Fig. 12(c) shows the construction prior to the geometric operation. Fig. 12(d) shows the construction after to the geometric operation.

At step ST51, structure 50 is instantiated to represent the arch of the object construction. The system inserts "arch" structure 50 as node N23 in scene graph 375 of Fig. 9(b). Spatial operator $S_{22}(X)$ in link L3 between scene graph nodes N22 and N23 encodes the spatial parameters between structures 50 and 53. Link L3 contains the

geometric boolean merge operator 61 specifying that structure 51 will be merged with door structure 53.

Cylinder structure 50 corresponds to features in image I101 of Fig. 6. It is attached to the door by equating its midpoint y-extent with the maximum y-extent of door structure 53 and its midpoint x and z extents with those of structure 53.

The width of the arch is to coincide with that of the door, so parameter *cyl_radiusA* is equated to structure 53 parameter *door_width*. To solve for *cyl_radiusB*, the height of the arch, feature point VF60 is marked in image I101 of Fig. 6 and corresponded to vertex element VE35, shown in Fig. 4(a). The depth of the cylinder is to correspond to that of the base and the door, so parameter *cyl_length* is equated to base structure 52 parameter *base_depth*.

At step ST53 modeling engine 13 solves for the arch height parameter *cyl_radiusB*.

At step ST55, the boolean merge operation between nodes N22 and N23 is executed by geometry engine 15. Given the hierarchy of the scene graph nodes, the arch structure is merged with the door structure. The merged structure is subsequently subtracted from the base structure. Fig. 12(e) shows the construction prior to the geometric operation. Fig. 12(f) shows the construction after to the geometric operation, which is the final construction. In the present example, with no more structures or images to process, process flow proceeds through steps ST56 and ST57. At step ST58, GE 15 does no geometric processing since all such operations were performed at step ST55. Process flow therefore terminates.

The above construction example is only but one of many solid modeling strategies for building the model of Fig. 12(f). For example, as an alternative to preformed solid objects, one might employ extrusions and revolutions instead. As shown in Fig. 13(d), the door structure could be implemented with the extrusion structure of Fig. 13(a). In this fashion, the rectangular extrusion profile X10 would be constrained to the front face base structure 52 in the same manner as was door structure 53. With straight line profile P10 orthogonal to the face of structure 52, an extrusion along its path produces the door structure, which is then subtracted from structure 52. Likewise, revolution of profile X40 around path P40, containing vertex element VE30 corresponded to vertex feature VF50 in image I101 of Fig. 6, produces a generated dome structure. Fig. 13(e) shows the final result.

Methods of Media Processing and Visualization

A set of system configurations and methods for processing and visualization of media utilizing the media processing engine (MPE) are disclosed.

The *phantom cursor* (PC) is an apparatus and process for acquiring a 3-space camera solution relative to any planar facet of a scene or object depicted in a 2D image. The PC is alternately utilized to solve for *structure* constrained to a 3-space plane given a known camera relative to the plane.

The PC apparatus comprises cursor graphics associated with 2D images, a user interface specification for creating and or modifying the cursor graphics, and an underlying 3-space construction frame and a parameter solution process. The PC apparatus embeds the fundamental geometry and camera construction and recovery processes of the MPE. This includes the annotation of 2-space imagery, the placement of and constraints on 3-space structures and cameras, the correspondence of 2-space features to 3-space elements, and the recovery of unknown parameters. The "phantom" terminology is employed to denote that structure components formed by the PC mechanism may or may not contribute to a construction model output.

The cursor graphics represent 2D-feature annotations to be associated with a 2D image. In the present embodiment, the phantom cursor graphic is an n -sided planar polygon in the plane of the image, consisting of n feature vertices (points) and n feature line segments (edges). For a given cursor graphic, the number n is either a built-in attribute of the system or is explicitly specified by the user. The system supports any number of simultaneous cursor graphics of varying dimension.

The 2D features of a PC graphic correspond to elements of a structure embedded in a 3-space construction frame. In the present embodiment, a quadrilateral structure embedded a reference plane, whose elements are corresponded to quadrilateral features in the image plane of a camera, is sufficient for Media Processing Engine 11 to recover the camera relative to the reference plane. Such a construction is also sufficient to recover the shape parameters of the structure embedded in the reference plane relative to a specified camera.

In the present embodiment, there are two primary ways that a cursor graphic is instantiated in an image. When the dimension n of the cursor graphic is known, a pre-formed cursor graphic of that dimension is instanced. When the dimension is unknown in advance, an interactive process is invoked, whereby the user interactively

forms the cursor by indicating the corner feature points of the cursor graphics directly onto the 2D image to which the cursor is associated.

Fig. 17(a) shows pre-formed quadrilateral ($n = 4$) PC graphic PG1. PG1 comprises four feature line segments F1, F2, F3, and F4. The intersections of these feature line segments determine the four corner feature vertexes VF1, VF2, VF3, and VF4 of the main rectangle. The extensions of the feature line segments beyond the intersections provide a visual aid to assist the user in manipulating the cursor. PG1 is yet to be associated with a 2D input image. Fig. 17(b) shows a default 3-space construction frame associated with the PG1. The present embodiment defaults the 3-space construction frame to a standard Cartesian coordinate system with x , y , and, z axes oriented as illustrated. Rectangular structure 69 embedded in the reference plane represents the imaging structure. Default camera C1 is initialized to some arbitrary internal and external parameterization. Element vertex VF1 is assigned as the first vertex of PS1 and is automatically corresponded to PG1 vertex feature VF1. Assuming a clockwise order of the remaining vertices of PS1, all the vertexes and line segments between PG1 and PS1 are automatically corresponded. These assignments and orientations are defaults and are fully alterable by the user or the application.

As an example of the processing and application of the PC, a plane in the room scene of image I200 of Fig. 18(a) is recovered. Fig. 18(b) shows image I200 with PG1 superimposed. Floor plane 303 depicted in the image is to be recovered. To recover a 3-space plane representing floor 303 from image I200, the user interactively reshapes phantom graphic PG1 superimposed within the image viewing window such that it appears to lie in perspective on the depicted plane of the floor. Fig. 18(c) and Fig. 18(d) show modified cursor graphic PG1 reshaped from its original square shape to a quadrilateral in the 2D image plane. This quadrilateral is now the image feature annotation set that relates the projection of the 3D reference plane and embedded structure construction into the image plane of the camera.

The 3-space construction of the present example is shown in Fig. 18(e). The x - z plane is designated by the application as the initial reference plane defining floor 303 in image I200. The reference plane is represented by structure 310 embedded in the x - z plane. In general, the orientation of the initial reference plane is set by either the application or explicitly by the user. PC structure PS1 is embedded in plane 310 and by default is centered on the 3-space world origin. In the present example, structure PS1 is a 2-parameter rectangle. Camera system C200 is attached to the input image I200 and is to

be recovered. PME 13 recovers camera C200 and phantom structure PS1 shape parameters relative to fixed reference plane 310.

Fig. 19 shows a flow diagram of the PC process. Upon entry at step ST100, PC graphic PG1, construction reference plane 310, 3-space PC structure PS1, and 3-space camera system C200 are established and initialized.

At initialization, PC graphic PG1 feature segments F1, F2, F3, and F4 and feature points VF1, VF2, VF3, and VF4 do not correspond to any feature of input image I200 - the cursor is "floating" as shown in Fig. 18(b). Unless explicitly overridden by the user, the system automatically corresponds PC graphic features to PC structure elements.

In Fig. 18 PG1 line segments F1, F2, F3, and F4 are assigned to PS1 edge elements E1, E2, E3, and E4, respectively. Alternate correspondences are equally valid as long as they maintain a proper clockwise or counterclockwise feature to edge assignment. The system also allows the user explicitly establish the correspondences if desired.

At step ST101, through user interface 12 and user-interactive input 25, the user interactively reshapes PC graphic PG1 superimposed on image I200. In the current embodiment and for the present example, user interface 12 allows the user to interactively "grab" line segment and point features to reshape the PG1 in a "rubber-banding" fashion. Cursor line segment features F1 through F4 and point features VF1 through VF4 are repositioned such that PG1 appears to lie in proper perspective within the targeted plane depicted in the image. For the present example, this is the depicted floor plane 303. The PC mechanism does not require image feature annotations to correspond directly to particular features seen in associated imagery. This allows the system to treat scenarios in which features in an image are incomplete, obscured, or do not exist. Execution of step ST101 establishes correspondence between PC graphic PG1, input image I200, and camera C200. With the correspondence between the PC structure PS1 and PC cursor graphic PC1 established by the system, the PC graphic PC1 is now considered "attached" as opposed to "floating".

At step ST102, parameter constraints are set implicitly by system or explicitly by user. If the plane recovery represents the first geometry-camera relationship established the PC automatically defaults one dimension of structure PS1 to an arbitrary scale value. This establishes implicit scale for the project. Alternately, partial or full true scale may explicitly set by the user with known or assumed values. For example, for partial scale, the user sets one dimension of rectangle PS1 to an actual known dimension of the scene or object. For full scale, the user sets two dimensions. In general, for an n -

sided phantom structure, n shape parameters may be set. When explicit scale is to be set, the user will typically align PC graphic features to observed features in the image that are of known (or to be guessed) dimensions.

At step ST103, photogrammetric modeling engine 13 is invoked to solve
5 for all unknown and unconstrained parameters of the overall PC construction. The shape parameters of PS1 as well as the intrinsic and extrinsic parameters of camera C200 are recovered.

Image Mosaics

Sometimes the field-of-view of a camera is not wide enough to capture an
10 entire scene in one image. For such scenes, a wide angle lens might be used, but such hardware is expensive and can still produce insufficient results. The system provides a processing modality that will mosaic together any number of images shot from a camera from the same viewpoint. This apparatus and method allows an individual to readily transform an ordinary camera into a wide-angle acquisition and visualization system.

15 In mosaic mode, media processing engine 11 accepts two or more 2D digital images 24 or 21 under the control of user-interactive input 25 through user interface 12. An example of input 24 is a user downloading images from a digital camera directly onto the host computer system. An example of input 21 is a user downloading digital imagery from a conventional film developing service (e.g. conventional 35mm
20 film) which offers digital output format and delivery directly over the Internet.

A flow diagram of the mosaic process is shown in Fig. 20. The process begins at step ST200 with the establishment of a 3-space mosaic construction frame and imaging plane. The construction frame constitutes the parametric 3D geometric representation of the mosaic. By default, the 3-space construction frame of the mosaic
25 apparatus is the default PC construction of Fig. 17(b). This establishes the x - y ($z = 0$) plane of the standard Cartesian coordinate system as the mosaic imaging plane.

At step ST201 the user enters the first input image via 12. The first input image is established as the *base* image of the mosaic construction. Process flow then proceeds to step ST202 and a system query for entry of another input image. By
30 definition, a mosaic comprises two or more images. If at step ST202 only one image has been loaded, process flow automatically proceeds back to step ST201 for entry of another image. If at step ST202 no additional images are required, process flow proceeds to image annotation step ST203.

To relate and mosaic together any two images, the user identifies, within each image, one or more planar polygonal regions in common with the other image. Such regions are marked in each image with the PC mechanism. Correspondences amongst regions and images are established by formation of PC groups, whereby each PC group
5 creates and shares a common geometric structure embedded in the mosaic imaging plane of the 3-space construction.

At step ST203, the first PC group is established. The user identifies a region common to two or more input images. Through user-interactive input 25 and interface 12 a PC is created and placed by the user clicking on n corner points of an
10 identified n -sided region while the system "rubber-bands" out piecewise adjoining line segments. By default, the system maintains PC and group accounting by mode – all PC's established during a given "form group" mode are equated. In general, groups may be set explicitly by the user or implicitly by an application.

An example of the user-interactive process at step ST203 is shown with
15 the set of input images of Fig. 21. The user inputs three images I300, I301, and I302 at steps ST201 and ST202. By choice of the user, image I300 is entered first, thus becoming the *base* image. The user visually identifies and selects the center "french door" region common to all three images. Fig. 22 shows input images I300, I301, and I302 with PC graphics superimposed. In image I300, the user marks four corner points of
20 the identified region starting from the lower-left corner point VF5 and proceeding in a clockwise order. A counter-clockwise layout could have been entered, as long as within a group, each PC annotation follows the same clockwise or counter-clockwise orientation. This produces a PC graphic PG2 with edge features F10 through F13 as shown. The system automatically extends the polygon edge line segments to span the dimensions of
25 the image. This enhances accuracy and provides an visually aids the user's adjustments to the PC graphic. The user may interactively adjust PC graphic features by moving the edge segments and or the corner points through user-interactive input 25 and interface 12. In image I301, the user marks the identified region starting from the same lower-left point orientation VF9 and proceeding in the same clockwise fashion, producing a PC graphic
30 PG3 with edge features F14 through F17. The same process is carried out with image I302, starting with point VF13, producing a PC graphic PG4 with edge features F18 through F21. In this example, the PC graphic of each image corresponds to the same image region – PG2, PG3, and PG4 are of the same group. With the user following a

consistent data input orientation, the system automatically corresponds image **I300** PC feature **F10** to image **I301** PC feature **F14** and image **I302** PC feature **F18**, and so on.

In 3-space, the construction of a mosaic consists of a common imaging reference plane and structure representing that plane, a PC structure for each PC group
 5 embedded in the imaging plane, and a camera system associated with each input image. At step **ST204**, the PC structure for the first PC group is embedded in the reference imaging plane structure.

A construction for the present example with three input images **I300**, **I301**, and **I302** is shown in Fig. 23. The mosaic imaging plane is represented by planar
 10 rectangular structure **50**. Cameras **C300**, **C301**, and **C302** correspond to images **I300**, **I301**, and **I302** and PC graphics **PG2**, **PG3**, and **PG4**, respectively. At step **ST204** the first (and only) PC structure, **PS2**, corresponding to PC group **PG2**, **PG3**, and **PG4**, is embedded in image plane structure **50** with its centroid spatially constrained to 3-space coordinate origin **52**. **PS2** is a quadrilateral, corresponding to the dimension of each PC
 15 graphic in the group. PC structure **PS2**, shown in greater detail in Fig. 24(a), is comprised of four vertices **VE5**, **VE6**, **VE7**, and **VE8** and four edge elements, **E5**, **E6**, **E7**, and **E8**.

The shape of PC structure **PS2** is determined by 8 independent parameters $xa, ya, xb, yb, xc, yc, xd, \text{ and } yd$. The coordinates of the vertices of PC structure **PS2** are
 20 a linear combination of these shape parameters as prescribed in Fig. 24(b). In general, an n -sided structure contains $2n$ parameters. If the structure is constrained to be rectangular or square, then the numbers of shape parameters are 2 and 1, respectively.

At step **ST204**, a base image and camera for the first PC group is selected. Unless set by the user or application, the base image defaults to be the first image entered
 25 at step **ST200**. In the present example, this is image **I300**. In 3-space, the mosaic composition of a set of images requires finding the camera solution of each image relative to a common image plane. By default, the base camera-image pair (**C300-I300**) is fixed such that its line-of-sight is orthogonal to the image plane (coincident with z-axis) and its point-of-view a fixed distance along the z-axis. In this configuration, the mosaic imaging
 30 plane and the image plane of the base camera are parallel.

Given the default spatial orientation and relationship of the base camera-image pair, the projection of the PC graphic of the base image establishes the correspondence and spatial orientation of PC graphics features with PC structure elements. For the present example, Fig. 24(c) shows how PC structure **PS2** is

corresponded to the PC graphic group comprised of PC graphics **PG2**, **PG3**, and **PG4**. Each edge element of **PS2** corresponds to 3 edge features. For example, edge element **E5** corresponds to edge features **F10**, **F14**, and **F18**.

At step **ST204** the shape parameters of the first PC structure are solved by modeling engine 13. Once solved, the values of these shape parameters are locked.

At step **ST205**, an inquiry to determine if additional PC groups are to be added. If yes, the process flow proceeds to step **ST206**, otherwise the process flow proceeds to step **ST208**.

At step **ST206**, the user adds one or more additional PC groups. At step **ST207** a PC structure is automatically added to the mosaic imaging structure for each additional group. These structures are constrained to lie in the imaging plane but are not explicitly constrained in position.

At step **ST208**, the shape and position parameters of all unsolved PC group structures and cameras are solved for by modeling engine 13. In the present example, all three input images are corresponded through a PC structure **PS2**. No additional PC groups are added. Cameras **C301** and **C302** are recovered by modeling engine 13 relative the solution of **PS2** and camera **C300** at step **ST204**.

At step **ST209**, visual reconstruction engine 16 composes the set of input images into a single mosaic image. In mosaic mode, output 26 of media engine 11 is a single image composition of the input image set. The composition of the input images is a projection of the images onto imaging plane 50 from the respective recovered cameras of the input images. In the present embodiment, the base image is first projected and texture-mapped onto the mosaic imaging structure. Subsequent camera projections are clipped against regions on the image plane texture-mapped, with only regions previously not texture-mapped rendered. The clipped images are composed using standard edge feathering techniques. In general, any blending and composition methodology may be employed.

Rendering Engine 17 displays the resulting composition. Fig. 25 image **I303** shows the resulting mosaic composition for the present example with of input images **I300**, **I301**, and **I302**. In addition to output 26, output 27 delivers the mosaic content output to the network 10. A mosaic database is three-dimensional and therefore the rendering of the mosaic may leverage the 3D structure. For example, the entire mosaic imaging plane construction be rotated or translated in a 3D viewing operation.

Image Collages

A collage is a composition of a *base (destination)* image with one or more ancillary *product (source)* images. The composition process entails “cutting” specified regions of source images and “pasting” them into specified regions in the destination
5 image. Examples of base images include single images representing scenes and/or objects to be modified and image mosaics of such images generated by the system or by an external process.

In collage mode, media engine 11 accepts two or more 2D digital images from the user at data input 24 under the control of interface 12. Alternately, images are
10 downloaded into the system at input 21 from network 10. The system outputs 2D image collage compositions 26 for rendering and viewing by the system, for storage, or sends 2D image compositions to network 10 through output 27.

Under the control of user-interactive input 25 and interface 12, the collage process entails the user identification and annotation of “cut from” feature regions in a set
15 of input source images and identification and annotation of corresponding “paste to” feature regions in an input base image. A system solution for source and destination region geometry and camera systems relative to a common collage imaging plane enables projective composition of source collateral with the destination collateral.

A process flow diagram for image collage construction and composition is
20 shown in Fig. 26. As an example, a collage is formed with scene image I200 of Fig. 18(a) as a base image and two product images I500 and I502 shown in Fig. 28. Fig. 29(a) shows the 3-space collage construction frame for current example.

At step ST300, the process begins with the establishment of a 3-space collage construction frame and imaging plane. In 3-space, the construction of a collage
25 consists of a common collage imaging plane and structure, one or more structures embedded in the imaging plane structure representing destination regions, and a camera system associated with each input image. The 3-space construction frame constitutes the 3D parametric geometric representation of the collage. By default, the 3-space construction frame of the collage apparatus is the default PC construction of Fig. 17(b)
30 with the x - y ($z = 0$) plane as the collage imaging plane. A shown in Fig. 29(a), planar rectangular structure 600 is embedded in the plane and serves as the collage imaging plane structure.

At step ST301 a base image is entered through user interface 12. In the present embodiment, the process assumes a collage based upon a single base image. If

additional scene images are desirable or required, the mosaic process (or other means) are employed to produce a base image that is a mosaic composition of a multiplicity of scene images. Source images may also be mosaic compositions. For the present example, scene image **I200** is entered. For base image **I200**, associated camera **C200** is established and constrained to a fixed 3-space position and pose parameterization. Its point of view is on the z-axis a fixed distance **601** from the construction frame origin and its line of sight is coincident with the z-axis and pointing toward the imaging plane **600**.

At step **ST302** a source (product) image is imported. In the present example, carpet image **I500** of Fig. 28 is imported. In the construction frame of Fig. 29(a), corresponding camera **C500** is instantiated with an unsolved default parameterization.

At step **ST303** the user annotates the base image and the current source image as a PC group.

As previously disclosed, PC graphics are entered on a point-by-point basis or as a pre-formed graphic from built-in library **18**.

For the present example, source image **I500** is annotated with PC graphic **PG5** to identify the source region of the current source image. Feature vertex **VF1** is arbitrarily assigned first and the remaining three vertices are marked in a clockwise direction. Scene image **I200** is annotated with PC graphic **PG6** to identify the corresponding destination region in the base image resulting in Fig. 27 image **I400**. For PC graphic **PG6**, feature vertex **VF5** is marked first and the remaining vertices are marked in a clockwise direction. The PC process corresponds **VF1** to **VF5** and the remaining features in the PC group according to the given input topology.

At step **ST304** a PC structure for the current PC group is embedded in the collage imaging plane and structure. By default, the dimension of the PC structure for the group is the number of vertices of the source region PC. In the present example, the dimension is four.

Given the fixed position and pose of the base image camera, the PC structure elements are automatically corresponded to base image PC graphic features through projective topological preservation. The PC structure elements are automatically corresponded to the source PC graphic features since the base and source PC graphic correspondences have been established. Modeling engine **13** solves for the unknown variable shape parameters of the PC group structure based on its correspondence with the fixed base camera. After the group PC structure parameters are recovered, they are

locked. Modeling engine 13 subsequently recovers the variable intrinsic and extrinsic parameters of all or selected source cameras.

In the present example, PC structure **PS3** is placed in imaging plane structure 600, as shown in Fig. 27. PC structure **PS3** vertex element **VE10** is
5 corresponded to PC graphic **PG5** vertex feature **VF1** and PC graphic **PG6** vertex feature **VF5**. **PS3** contains 8 independent shape parameters like structure **PS2** of (a). These variable shape parameters are recovered based on the fixed position and pose of camera **C200** attached to base image **I200**. With these structure parameters constrained, camera **C500** attached to source image **I500** is recovered.

10 At step **ST305**, the system queries as to whether additional source images are to be processed. If yes, process flow proceeds back to step **ST302** and the input of another source image. If no, process flow proceeds to step **ST306**. In the present example, process flow proceeds back to step **ST302** with the input of source image **I502** of Fig. 28. At step **ST303**, Fig. 27 base image **I400** is annotated with PC graphic **PG7**.
15 Vertex feature **VF9** is entered as its first vertex. Source image **I502** is annotated with PC graphic **PG8** with vertex feature **VF13** as its first entry. At step **ST304** PC structure **PS4** is inserted in imaging plane structure 600. Again, the structure placed contains 8 independent shape parameters like the structure **PS2** of (a). The system corresponds PC graphic **PG7** vertex feature **VF9** to PC graphic **PG8** vertex feature **VF13** and PC
20 structure **PS4** vertex element **VE20**. PC structure **PS4** variable shape parameters are recovered by modeling engine 13 based on the fixed position and pose of camera **C200** attached to base image **I200**. With these structure parameters constrained, the variable intrinsic and extrinsic parameters of camera **C502** attached to source image **I502** are recovered.

25 At step **ST306**, reconstruction engine 16 prepares the collage database for composition and rendering. All source images are clipped against their respective PC graphic regions. This constitutes the "cut" portion of the "cut-and-paste" collage processing paradigm. By default, the interior region of a PC graphic is retained as the source imagery to be composed with the base imagery. Alternate selections are made by
30 the user or the application program. In general, any combination of clip regions can be selected. In the present example, image **I500** is clipped against **PG6** and the interior region of the PC graphic is retained. Likewise, image **I502** is clipped against **PG8** and the interior region of the PC graphic is retained

At step ST307, Rendering Engine 17 composes and renders the base image with all source images. Clipped source image regions are composed with their respective base image destination regions by projecting them onto the base imaging plane through their recovered cameras.

5 In the present example, base image I200 is projectively texture-mapped onto image plane 600 through camera C200. Then, source image I500 is projectively texture-mapped onto it corresponding structure PS3 through camera C500 and source image I502 is projectively texture mapped onto structure PS4 through camera C502. Upon projection, source regions may be combined with destination region using any
10 desired blending operation. In the present example, source pixels replace destination pixels. The final collage is Fig. 30 image I401.

 Rendering engine 17 implements multiple image layer composition techniques to resolve hidden surface and hidden object situations during collage composition. Commonly available image region selection algorithms and techniques are
15 incorporated to generate masking layers. These layers are known as *alpha channels*. During composition, these masking layers determine which pixels of source and destination imagery contribute to the final collage composition. Rendering engine 17 processes alpha channel images as an integral component of its projective composition methods. Rendering engine 17 utilizes some of the same techniques in the rendering of
20 full 3D constructions.

 As an example of alpha channel processing, Fig. 31 shows room scene image I600 into which television image I601 will be collaged. Image I602 of Fig. 32 shows a collage composition of images I600 and I601. In image I602, source "television" pixels of image I601 are seen obscuring "couch" pixels, a visibly unrealistic
25 and undesirable result. This area is pointed to as region R1. Image I603 of Fig. 32 shows an alpha channel image generated by the user with a system incorporated image region selection tool or a standalone image processing tool such as [4]. In image I603 the "couch" region (black pixels) is isolated from the remainder of the scene (white pixels). In the rendering process, rendering engine 17 projects alpha mask image I603 from the
30 perspective of the recovered scene image camera onto the collage imaging plane prior to rendering the source region of image I601. Upon rendering image I601, destination pixels are replaced only if their corresponding alpha image pixels of image I603 are white. Image I604 of Fig. 33 shows the final result, with the couch pixels preserved.

Image I604 also shows utilization of the alpha channel image I603 to assist in modifying the depicted color of the couch.

3D Scene Construction

The above-described mosaic and collage methods form image compositions based on 3-space constructions with a single imaging plane. The 3D scene construction methods disclosed below extend these concepts to constructions that are assemblages of multiple planar and volumetric structures in 3-space. Scene constructions are assembled from one or more input images.

Scene construction methods are presented in the context of an application specific implementation of the current embodiment of the system. The application example given is targeted for the construction of a 3D architectural scene. An example room interior construction is shown. This application and associated methods are just one example of the general applicability of the MPE to a vast range of scene and object construction scenarios.

A process flow diagram of a general 3D scene construction process is shown in Fig. 34. As an example, a 3D geometric construction for the scene depicted in image I700 of Fig. 35 is created. The resulting geometric construction is shown in Fig. 36.

At step ST400 the user imports a scene image through user interface 12. At step ST401 the system determines if the current input image is the first. If it is, then process flow proceeds to step ST402. Otherwise, process flow proceeds to step ST403.

At step ST402 a PC process is initiated for the recovery of an initial scene reference plane and structure and camera system for the current scene image. The present application is pre-programmed to begin construction of a room environment from a root floor plane. This "floor-up" method defaults the horizontal x-z plane of the PC Cartesian coordinate system as the floor reference plane. In general, an application requiring only the recovery of a wall surface might initialize the y-z or x-y plane as the initial reference plane. Alternately, the user may explicitly specify the orientation of the initial reference plane.

By default, a planar rectangular structure is automatically placed by the system to represent the reference plane. The reference structure contains two variable shape parameters set by the system at initialization. The values for these parameters are selected such that the reference plane is large enough to encompass the field-of-view of

the current scene camera. Initially, the size parameters are set to arbitrarily large numbers. These values are either explicitly modified by the user or are procedurally modified by the system once the field-of-view of the designated scene camera is recovered. In the latter case, the application determines if the geometry of the structure is clipped by the image window of the camera, when back-projected into the camera. If so, the system enlarges the geometry until this condition is eliminated. This procedure thus ensures that the size of the structure is large enough to span the extent of the view port of the camera.

To recover the floor plane geometry and scene camera parameterization, a PC graphic is placed by the user in the main scene image and a corresponding PC structure is placed in the default floor reference plane. The PC process is executed with modeling engine 13 solving for the variable shape parameters of the PC structure and intrinsic and extrinsic variable parameters for the camera associated with scene image. In the PC process, the user enters known, guessed, or measured values for PC structure shape parameters. A scene takes on true-to-scale proportions if actual measured values are provided.

For the present example, at step **ST400** scene image **I700** is imported. This is the first input image and process flow proceeds to step **ST402**. At step **ST402**, planar rectangular structure **900** from built-in library **18** is inserted by the system in horizontal *x-z* plane of the coordinate frame. Within structure **900**, a planar rectangular structure from library **18** is embedded as PC structure **PS10**. **PS10** is spatially constrained to be centered at the origin of the coordinate frame. **PS10** contains two variable shape parameters **S1** and **S2**. Camera **C700**, corresponding to image **I700**, is instanced with unsolved default parameters. PC graphic **PG10** is placed in scene image **I700**, as shown in Fig. 35. Through user-interactive input **25** and interface **12**, the user interactively shapes PC graphic **PG10** in scene image **I700** to appear to lie in the depicted floor. Fig. 36 shows the 3-space construction with floor plane structure **900**, PC structure **PS10**, and camera **C700** established by the PC process. PC graphic **PG10** features **F81**, **F82**, **F83**, and **F84** correspond to PC structure **PS10** elements **E81**, **E82**, **E83**, and **E84**, respectively.

The scene construction is calibrated to real world dimensions through **PS10** variable shape parameters **S1** and **S2**. In image **I700** the user has aligned **PG10** such that dimension **S1** corresponds to the width of the depicted hallway entrance and **S2** corresponds the distance between the wall of the hallway entrance and the end of the

fireplace. The user supplies known measured values or guessed values for these parameters. Modeling engine 13 solves for all unknown parameters of the PC construction. Floor structure 900 and scene camera C700 intrinsic and extrinsic parameters are recovered relative to established structure 900 and calibrated to produce
5 the scale dictated by the submitted shape parameters of PC structure 900. Fig. 37 shows the construction scene graph 275 with structure 900 in "floor" node N10.

At step ST403, the system queries as to whether additional structures are to be added. If yes, process flow proceeds to step ST404. Otherwise, process flow proceeds to step ST407.

10 At step ST404 the next structure of the 3-space construction is selected and placed. Structure selection is explicit by the user or implicit by the application.

In the present example, the user places a wall for the "left" side of the room. Planar rectangular structure 902 instanced from built-in library 18 is selected by the user as a "wall" object. The present application is pre-programmed to place "wall"
15 structures in an orthogonal orientation relative to "floor" structures and to build-up from floor structures. Structure 902 is inserted into scene graph 275 as "left-wall" node N12, a child of floor node N10. The system constrains the minimum y-extent of plane 902 to the surface of floor plane structure 900. As with reference plane 900, structures added to the scene are initialized to default or procedurally generated sizes. Structure 902 has two
20 shape dimensions S3 and S4, corresponding to *wall_width* and *wall_height*, respectively. Unless explicitly overridden by the user, the application sets *wall_width* and *wall_height* to values large enough that the extents of these structures cover the field-of view of the 2D image window as viewed by the scene camera C700.

At step ST405, the full position and shape parameterization of an added
25 structure is resolved.

To determine the complete set of placement and dimensions parameters of an added structure, the user annotates features in the scene image that correspond to elements of the new structure. In a typical application, the system will request information from the user specific to the context of the construction underway. In the
30 present example, to solve for the exact positioning of structure 902 relative to structure 900, the system requests the user annotate input image I700 with an edge feature line segment that indicates where the wall and floor meet. In image I700, the user annotates line segment F70. The system knows this edge element belongs to a "floor-wall" juncture, so image feature F70 is automatically corresponded to structure 902 edge

element E70. Given that floor plane 900 and camera C700 are known, the F70-E70 correspondence pair is sufficient to fully place structure 902. The system then queries the user to provide image annotations for the left, right and top edges structure 902 to resolve its shape parameters. If none are provided, as is the case here, then default or system
5 procedurally derived dimensions are retained.

At step ST406, modeling engine 13 solves for unknown parameters of the construction. In the present embodiment, the system locks all previously solved for parameters. As an option, the system allows for all or select groups of solved parameters to be re-solved. In the present example, at the insertion of wall plane 902, parameters
10 pertaining to reference plane 900 and camera C700 are locked. The unknown and unconstrained parameters of spatial operator $S_{12}(X)$ in the link between scene graph nodes N10 and N12 are recovered.

Process flow returns to step ST405 and the system queries as to whether more structure are to be added. In present example, two more structures, planar "wall"
15 structure 903 and volumetric "fireplace" box 904, are added. Planar rectangular structure 903 is placed orthogonal to floor structure 900. The position of plane 903 relative to plane 900 is established with user-supplied feature annotation F71 in image I700. Image feature F71 is automatically corresponded to structure 903 edge element E71. The user also annotates image feature edge segment F72 corresponding to structure 903 element
20 E72 to place the right edge of the wall 903. Structure 903 is inserted into scene graph 275 as "back-wall" node N11, a child of floor node N10, with spatial positioning given by spatial operator $S_{11}(X)$. The next structure added to the construction is three-parameter volumetric box structure 904, which becomes "fireplace" node N13 in scene graph 275, a child of left-wall node N12. By default, the application constrains the minimum y-extent
25 of the box structure to floor structure 900 and set "box-height" dimension S5 equal to the height value of wall structure 903. The application also sets the minimum x-extent of structure 904 to the plane of left-wall structure 902, constraining the back of the fireplace to the face of the wall. User placed image feature annotations F73 and F74, corresponding to structure elements E73 and E74, determine the width and depth
30 dimensions of fireplace structure 904. Modeling engine 13 solves for all remaining unconstrained and unsolved parameters, including spatial operator $S_{13}(X)$ in the link between scene graph 275 nodes N12 and N13.

A scene construction contains one or more scene images. The user may elect to annotate an image at any time, in which case process flow proceeds to step
43

ST405. Alternately, at step ST407, the system queries the user as to whether a scene image is to be annotated. If affirmative, process flow proceeds to step ST5. If negative, process flow proceeds to step ST408, where the system queries the user as to whether a scene image is to be added to the construction. At step ST408, if affirmative, process flow proceeds back to entry point step ST400. Alternately, the user may add scene images at any time, at which point process flow proceeds to step ST400. The addition of an image also means the addition of a camera system attached to the image. At step ST400, upon user entry of the image through interface 12, process flow proceeds to step ST403 through step ST402. At step ST408, if negative, process flow proceeds to step ST409.

At step ST409, with all scene structures specified, placed, and unknown structure shape, spatial positioning, and camera parameters resolved, the system performs all geometric operations on the scene construction. The scene graph of the scene construction is traversed and the geometric operations to be performed between structures are extracted from the links of the scene graph and are executed by GE 15. A traversal of Fig. 37 scene graph of 275 shows that all links between structure nodes contain boolean union operator 60. The scene construction of Fig. 36 depicts the scene 3D construction after traversal of the graph and execution of all union operators.

In the present embodiment, there is only one 3D construction frame processed at a time. The existence of multiple image-camera systems means that image feature annotation sets of different images may correspond to common structure elements. The parameter space to be solved is increased by the parameterization of additional cameras.

Intelligent Objects and Intelligent Scenes

Intelligent objects are object constructions whose functional components are structurally modeled and subject to physical simulation through variation of the variable parameters of their composition. An example of an intelligent object is a cabinet construction containing a drawer construction that is parameterized to slide open and close.

Intelligent scenes, analogous to intelligent objects, are scene constructions whose functional components are structurally modeled and subject to physical simulation through variation of the variable parameters of their composition. An example of an

intelligent scene is a room interior construction containing a door construction that is parameterized to swing open and close.

Media Integration Methods

The system provides seamless integration, visualization, and simulation amongst the various construction modes and types. This includes the integration of image mosaics, image collages, 3D scene constructions, and 3D object constructions. Constructions are integrated within a single project or as the coalescing of a number of separate projects. The latter scenario is typically implemented using a client-server processing model, whereby construction components are interchanged between a multiplicity of processing nodes and projects.

Central to media integration processing is the merger and manipulation of construction databases comprised of scene graph and ancillary data structures. Fig. 39 illustrates a media integration and simulation process flow.

At step ST900, the system queries as to whether a valid scene graph database resides in unit 14. If true, process flow proceeds to step ST904 and the import of an insertion database. If not, process flow proceeds to step ST901 where a decision is made whether to construct a new scene database or load on existing saved scene database. If the user elects to create a new database, process flow proceeds to the 3D scene construction process at step ST902. Otherwise, process flow proceeds to step ST903 and the import of a scene database into unit 14.

At step ST904 an object database is imported and pre-processed. Imported databases range from complete projects that include imagery, geometry and camera models, and ancillary data to sparse projects that might include only one of these components. For example, the receiving application might import imagery of an object but not the object geometry; depending on the application configuration, geometry for a construction related to an imported image may be internally sourced from built-in library 18. This reduces the amount of data transferred over network 10.

At step ST905 the method of object placement is selected. The placement of an object is either under the control of the application or the discretion of the user. If initial placement is not under the control of the user, process flow proceeds to step ST907 where objects are assigned an initial position within the 3-space coordinate system procedurally determined by the application program. Otherwise process flow proceeds to step ST906 where the type of user-interactive object placement is selected.

Object placement is established by the user object with a point-and-click mouse interface through user input 25 and interface 12. The anchoring of source and destination constructions is accomplished by selection and correspondence of features of source images and/or elements of source models to features of the destination scene images and/or elements of destination scene models. For the source, the user interactively selects one or more image feature annotations or object elements as anchor reference points. For the destination, the user interactively selects geometric elements of the scene model, existing scene image feature annotations, or places new image feature annotations in one or more destination images. Modeling engine 13 solves for all unknown and unconstrained parameters defining the shape and spatial interrelationships between merged construction components.

Scale factors between source and destination models are established by the method of placement employed and the known and recovered values of the established parameter space. In present embodiment, the system employs two primary methods of placement, *true-to-scale* and *force-fit-scale*. True-to-scale processing is based on the use of explicitly known values of source and destination model parameters. Force-fit-scale processing is based on the use of implicit and recovered values of source and destination model parameters governed by placement constraints.

At step ST906 the type of user-interactive placement is selected. If the "explicit scale" processing is selected process flow proceeds to step ST908. Otherwise process flow proceeds to "force-fit scale" processing at step ST909.

At step ST908 true-to-scale object insertion is executed. In this mode, source and destination model dimensions are known or assumed. To merge models of known dimension, the user identifies and equates feature and element *anchors* in source and destination imagery and geometry. Modeling engine 13 solves for the values of unknown spatial operators and camera models. The absolute scale between merged source and destination models is preserved. A typical use scenario of explicit scale is when a scene of known true dimensions is inserted with an object of known true dimensions.

At step ST909 force-fit scale object insertion is executed. In this mode, a destination region is specified which allows modeling engine 13 to size as well as position the source model into the destination model. The scale factor between merged source and destination constructions is established by the proportions of the destination

region. A typical use scenario for this method is the insertion of an object of unknown dimensions into a scene.

As an example of the overall process flow of Fig. 39, the integration of the rug object depicted in image **I500** Fig. 28 within scene **I200** of Fig. 18(a) is executed.

5 At step **ST900** a new scene database is constructed. Process flow proceeds to step **ST902** and the 3D construction process of Fig. 34 is executed. In that process, at step **ST402**, the PC construction process of Fig. 18 is executed. Analogous to Fig. 18(e), the 3-space construction of Fig. 42(c) is produced, with recovered floor plane structure **700**, embedded PC structure **PG20** and recovered camera model **C200** for image **I200**.
10 Data structures unit **14** contains scene graph **575** with a single node **N100** containing floor structure **700**, as shown in Fig. 42(a). The scene is scaled to true measured dimensions through the PC process, with the PC graphic aligned to known image feature reference points and the actual measured dimensions of those features entered for the corresponding parameters of the PC structure.

15 At step **ST904** an imported object database comprises rug source image **I500** of with corresponding PC graphic **PG6**, and rug shape parameters *rug_length* and *rug_width*. The present application example is pre-configured to import "rug" databases. As such the system is configured to internally supply planar rectangular structures from built-in library **18** for "rug" object constructions. With the import of image **I500**, camera
20 model **C500** is established. In the present example, no camera model parameters are imported with image **I500**; camera **C500** is internally initialized with no known model parameters assumed. The application automatically assigns planar rectangular structure **750** from built-in library **18** to incoming PC graphic **PG6**, establishing the geometric model of the rug object. Vertex element **VE20** of object structure **750** is identified as the
25 correspondence to **PG6** vertex feature **VF5**. A direct correspondence between all **PG6** edge and vertex features and structure **750** edge and vertex elements is established.

 At step **ST905**, the user elects to interactively place the rug object. At step **ST906** the user elects to place the rug using its imported true dimensions *rug_length* and *rug_width*. At step **ST908** the user places cross-hair image features **933** in scene image
30 **I200** to establish the destination anchor point for the rug object on the depicted floor, as shown in image **I800** of Fig. 40. For the source anchor point, the user selects PC graphic **PG6** feature point **VF5** directly on image **I500** of Fig. 28, or vertex **VE20** directly on object geometry **750**. The application also texture maps image **I500** onto geometry **750**, allowing the user to select **VF5** and **VE20** concurrently and directly from a 3D texture-

mapped model presentation. The selected source and destination anchor points are then equated, completing the source-to-destination correspondence and the executing the insertion is executed. Modeling engine 13 solves for all unknown camera and spatial operator parameters to place rug structure. The imported rug shape parameters
 5 *rug_length* and *rug_width* explicitly specify the true size of the rug object within the scene of known dimensions.

Fig. 42(c) shows rug object structure 750 inserted and constrained to floor structure 700. Two cameras are shown. Camera C200 for scene image I200 and camera C500 for rug image I500. In Fig. 42(b), node N101 containing structure 750 is inserted
 10 into scene graph 575 as a child of floor node N100, reflecting the insertion of the rug object into the scene. The spatial relationship between structures N100 and N101 is given by the spatial operator $S_{10}(X)$ in the link between the nodes. The values for the variable parameters of $S_{10}(X)$ are established by explicit geometric constraints and computation of modeling engine 13. In the present example, the y translation component of $S_{10}(X)$ is set
 15 to zero, constraining structure 750 to lie in the plane of parent structure 700. The x and z translation and y rotation components of $S_{10}(X)$ are recovered by modeling engine 13 to place the rug at anchor point 933, as shown in image I801 of Fig. 40.

An alternate example demonstrating the force-fit-scale processing of step ST909 is disclosed. The method combines destination and source model creation and
 20 integration through a shared PC process. Combined is the PC process for finding a camera model and reference plane in a 3-space construction for an input scene image and a "force-fit" procedure for merging additional 3-space constructions. The user interface procedure is similar to that of the disclosed 2D image collage process.

The process is exemplified with the previous example of integration of the
 25 "rug" object of Fig. 28 within scene I200 of Fig. 18(a). At step ST900 process proceeds to step ST901. At step 901, the user elects to create new geometry and process flow proceeds to step ST902.

At step ST902 a destination reference plane is selected by the user and a PC process is initiated for the recovery of the initial destination scene reference plane,
 30 structure, and camera system relative to the current scene image. The application could be more specifically tailored – such as a "place rugs on floors" or a "place pictures on walls" application, in which case the destination orientation is a built-in attribute of the application. A PC graphic is placed in the scene image and shaped by the user to define the destination region into which an object to be inserted. A corresponding PC structure

is placed in the selected reference plane and structure. Fig. 43 shows the 3-space construction.

At step **ST902**, the user explicitly indicates that the destination of an object is a horizontal "floor" plane and the application defaults the horizontal x - z plane of the PC Cartesian coordinate system defaults as the floor reference plane. Planar rectangular structure **800** from library **18** is inserted by the system in horizontal x - z plane of the coordinate frame. If, for example, the picture product of Fig. 28 image **I502** is to be placed within a vertical wall structure in the same scene, the user would explicitly specify a vertical "wall" plane and the application would default the horizontal y - z plane of the PC Cartesian coordinate system defaults as the wall reference plane. Scene image **I200** of Fig. 18(a) is annotated with PC graphic **PG5** to identify the destination region in the scene image, as shown in image **I400** of Fig. 27. Feature vertex **VF1** of **PG5** is marked first and the remaining **PG5** vertices are marked in a clockwise direction. Within structure **800** planar rectangular PC structure **PS30**, corresponding to **PG5**, is placed centered about the coordinate system origin. Camera **C200** of destination scene image **I200** is initialized with unsolved default parameters. Through user-interactive input **25** and interface **12**, the user interactively shapes PC graphic **PG5** in scene image **I200** such that the PC graphic region represent the outline of the region to be occupied by a source object or components of a source object, relative to the reference structure, and as viewed in perspective.

At step **ST904** an object database is imported and pre-processed. In the present example, the imported object database consists of rug product image **I500** of Fig. 28 and corresponding PC graphic **PG6**. Values for shape parameters *rug_length* and *rug_width* may or may not be imported. No camera model parameters are imported with image **I500**. The application example is pre-configured to import "rug" databases. As such, the system is configured to internally supply planar rectangular structures from built-in library **18** for "rug" object constructions. In "force-fit" mode, the application defaults to using the current PC structure geometry. In the present example, this is **PS30**. The application automatically assigns planar rectangular structure **PS30** to incoming PC graphic **PG6**, establishing the geometric model of the rug object. Vertex element **VE30** of object structure **PS30** is identified as the correspondence to **PG6** vertex feature **VF5**. A direct correspondence between all **PG6** edge and vertex features and structure **PS30** edge and vertex elements is established.

Fig. 38(a) shows an example intelligent object assembly constructed by the system. The assembly contains dynamic spatial operators. The model assembly consists of main box structure 90, box cover structure 91, and box drawer structure 92. The object assembly is encoded as scene graph 300 with structure 90 in node N15, structure 91 in node N16, and structure 92 in node N17. Spatial operator $S_6(X)$ between nodes N15 and N16 specifies the spatial relationship between the box and its cover. Spatial operator $S_7(X)$ between nodes N15 and N17 specifies the spatial relationship between the box and its drawer. Composed within operator $S_6(X)$ is *cover_rotate_z* parameter 94 that specifies rotation of the cover structure about the z-axis linking the cover and the box. Composed within operator $S_7(X)$ is *draw_trans_x* parameter 93 that specifies translation of the drawer structure along the x-axis relative to the drawer coordinate frame. Physical-based modeling attributes are also attached to the spatial operators. Variable parameters *cover_rotate_z* 94 and *draw_trans_x* 93 are manipulated through user-interactive input 25 and interface 12 and application programming to simulate the functionality of these components of the model assembly.

Interactive simulation functions of the system include the spatial repositioning of scene models and object models relative to each other. As shown in Fig. 41, the rug object of Fig. 28 image I500 is interactively re-positioned within the floor plane of the scene to simulate various placement scenarios. The scene is represented by scene graph 575 of Fig. 42 (b). Repositioning of the rug object is accomplished by interactive variation of the variable parameters of $S_{10}(X)$ while retaining its fixed constrained parameters. Fig. 40 image I801 shows the rug within the scene at its user established anchor point 933. Fig. 41 images I802 and I803 are two display frames rendered from rendering engine 17 showing the rug object displaced along the floor from its initial anchor point 933.

Client-Server System Model

Disclosed is a client-server processing and communication model suitable for deployment of the MPE and methods over a wide range of network-based applications. The MPE and methods are not limited to such an implementation.

As shown in Fig. 49, one or more client processing nodes and one or more server processing nodes are connected to a computer network, such as the Internet. A *client node* CN100 is a computer system or other network appliance connected to a computer network. It is capable of communicating with one or more server nodes and

other client nodes on the same network. A *server node* SN200 is a computer system or network appliance connected to a computer network. It is capable of communicating with one or more client nodes and other server nodes on the same network. Client nodes and server nodes embed MPE 11.

5 Client node CN100 receives and sends digital information 802 from and to network 10.

 Digital information 802 received from network 10 is comprised of 2D images 21, 3D geometric models 20, and ancillary data 22. Digital imagery 21 is downloaded to a client node from a system server node, another system client node, or
10 any other node on network 10. Geometric models 20 are parametric and non-parametric, and downloaded from a server node SN200 or other client node CN100 and generated by 11 at those nodes. Parametric models generated by 11 are structure assemblages interchangeable between client and server nodes. Parametric and non-parametric models generated by other means, such as other modeling software programs or hardware
15 scanning devices, may also be downloaded from any network node at input 20. Data 802 sent to network 10 is comprised of user 2D images 24 and user 3D parametric models 23. Digital input 804 is digital information a client node receives from a user. This input includes user interactive input 25, user digital images 24 imported from sources such as digital cameras and analog-to-digital scanners, and 3D geometric models 23 imported
20 from external medium such as CDROM. It also includes system project databases and ancillary data 28.

 A server node SN200 receives and sends digital information 803 from and to network 10. Digital information 803 received from network 10 is comprised of 2D images 21, 3D geometric models 20, and ancillary data 22. Digital imagery 21 is
25 downloaded to a server node from a system client node, another system server node, or any other node on network 10. Geometric models 20 are parametric and non-parametric, and downloaded from a server node or other client node and generated by 11 at those nodes. Parametric and non-parametric models generated by other means, such as other modeling software programs or hardware scanning devices, may also be downloaded
30 from any network node at input 20. Digital information 803 sent to network 10 is comprised of user 2D images 24, and user 3D parametric models 23. A server node receives digital information 805 from a user. This includes user interactive input 25, digital images 24 imported from sources such as digital cameras and analog-to-digital

scanners and 3D geometric models 23 imported from external medium such as CDROM. It also includes system project databases and ancillary data 28.

A client node executes *client-side application* software CA based on the MPE and processing methods disclosed. In a typical configuration, a client node
5 downloads CA from a server node on network 10 or from other data storage and delivery medium such as CDROM. The client-side application program CA embeds some or all of media processing engine 11 capabilities and features. CA is capable of generating, composing, and visually rendering 2D image mosaics, 2D image collages, and 3D object models, 3D scene models from 2D digital images based on the disclosed system and
10 methods. CA is capable of dynamic visual and physical-based simulation of 3D object and scene models generated within the node, received from the network or other sources, and compositions of node generated and node imported content.

A server node executes *server-side application* software SA based on the MPE and processing methods disclosed. The server application program SA embeds
15 some or all of the media processing engine 11 capabilities and features. SA is capable of generating, inter-composing, and visually rendering 2D image mosaics, 2D image collages, 3D object models, 3D scene models from 2D digital images. SA is capable of dynamic visual and physical-based simulation of 3D object and scene models generated within the node, received from the network or other sources, and compositions of node
20 generated and node imported content.

In a typical configuration, server nodes are responsible for disseminating *client-side application* software CA components of 11 executed by client nodes to client nodes. The components and type of processing carried out by individual client or server nodes and the data transactions between client and server nodes is a function of the target
25 application.

E-Commerce Merchandise Visualization and Information System

A product visualization, simulation, and information communication system will now be described. Based on the media processing engine (MPE), methods, and client-server processing and communication model, the disclosed merchandising
30 system connects product *consumers*, (e.g. shoppers, buyers) with product *purveyors* (e.g. manufacturers, retailers).

Users can visualize actual product application environments, into which purveyor product representations are seamlessly integrated, visualized, and simulated.

The system also allows shoppers to generate 2D image compositions and 3D constructions of products directly from 2D imagery in the event that such representations are not already available.

5 The system may operate as a stand-alone application or be integrated as a component in an existing online e-commerce system.

The described embodiment of the e-commerce merchandising system is shown in Fig. 50. In a client-server configuration over network 10, product shoppers are associated with client nodes CN100 and product purveyors are associated with server nodes SN200. Client and server processing nodes may also operate in stand-alone mode,
10 removed from network 10.

In the context of a merchandising system, client nodes CN100 are called **SHOP** nodes and product purveyor nodes SN200 are called **SELL** nodes. As an example deployment scenario, **SELL** nodes are the e-commerce web sites of product manufacturers, retailers, and the likes, and **SHOP** nodes are consumers and the like with
15 an online personal computer or other web-browsing enabled device.

A **SELL** node functions as a content creation station, a content server, and a program server. A **SELL** node implements the full range of media processing engine 11 digital content creation, visualization, and dissemination capabilities. In the current client-server embodiment, **SELL** nodes distribute (serve) merchant-tailored processing engine 11 program components **S-PROG** to **SHOP** nodes, enabling **SHOP** nodes with
20 processing engine 11 programs **C-PROG**. Alternately, **SHOP** nodes import their application software **C-PROG** from other mediums, such as CDROM.

In a collaborative content-creation workgroup configuration over network 10, **SELL** nodes share their content and project databases 20, 21, 22, and 27 with other
25 **SELL** nodes.

SELL nodes create, package, and distribute 2D and 3D digital representations and ancillary information of the products and services associated with the purveyor. Such media includes all combinations of 2D product images, 3D product models, form and function parametric data, and other ancillary product information.
30 Ancillary information includes media typically associated with product catalogs and brochures as well as video and audio presentations. Three principal media packages created and served from **SELL** nodes to client **SHOP** nodes are *Intelligent Image Packages IIP*, *Intelligent Object Packages IOP*, and *Intelligent Ancillary Data packages*

IDP. Both **SELL** and **SHOP** nodes may also distribute all forms of data individually and not as a package.

Intelligent image packages **IIP** are 2D digital images or image compositions packaged and served with parametric data that enable a full range of 2D and 3D visualization and simulation capabilities at both **SELL** and **SHOP** nodes. For example, a product purveyor offers the rug product of image **I500** of Fig. 28 in several choices of patterns and size. The purveyor **SELL** node can serve an intelligent image package **IIP** containing one or more images of the rug depicting color and pattern options along with parametric shape and color option data.

Intelligent Object Packages **IOP** are packages of data associated with 3D object and scene constructions, including scene graphs, geometric structures, texture maps, camera models, and parametric data controlling construction form and function. **IOPs** enable a full range of 3D visualization and simulation capabilities at both **SELL** and **SHOP** nodes. As an example, a **SELL** node offers cabinet product **90** depicted in image **I900** of Fig. 44. An intelligent object construction of cabinet **90** is shown in Fig. 38, with a single parametric drawer component **92** and cover component **91** modeled. As an intelligent object package, cabinet **90** is served by the **SELL** node with its scene graph **300**, imagery **I900**, geometric structures, camera models, shape parameters, and function parameters (draw_trans_x, cover_rotate_z).

Intelligent Ancillary Data Packages **IDP** are portfolios of ancillary information related to products and services distributed from **SELL** nodes. Ancillary information includes textual, audio, or video descriptions of products and services. An **IDP** is packaged and served with **IOPs** and **IIPs** or separately.

IDP information is presented by the system through graphical display mechanisms. The primary **IDP** displays are 2D image overlay "pop-up" mechanism **PUP2** and 3-space embedded 3D graphical display pop-up mechanism **PUP3**. A **PUP2** is a 2D image overlay similar to 2D graphical overlay and dialog mechanisms common to windows-based applications. A **PUP3** is a 3D a texture-mapped geometric "billboard" object that is embedded and rendered as an additional construction component of a 3D scene. **PUP2** and **PUP3** mechanisms are attached to scene graph unit **14** nodes of 2D image compositions and 3D object and scene constructions. **SELL** nodes generate, store, and disseminate **PUP2** and **PUP3** displays.

Fig. 30 shows collage composition image **I401** with **PUP2** graphic overlay **PUP2-10** attached to the rug object. Fig. 29(b) shows corresponding collage construction

scene graph 250 with **PUP2-10** attached to rug node **N301**. Fig. 47 shows an example **PUP3** graphical pop-up display **PUP3-30**. The system allows the **SELL** node to create or import 3D geometry to represent a **PUP3**. The system is not limited to any particular **PUP3** display geometry. For the present example **PUP3-30**, product information is
5 displayed on one face of the display geometry. Fig. 48 shows scene image **I990** with 2D overlay display **PUP2-20** attached to wooden CD cabinet product **90** and 3D pop-up display **PUP3-30** attached to wooden storage box product **91**. Fig. 38(b) shows **PUP3-30** attached to node **N15** of scene graph **300**.

PUP2 and **PUP3** mechanisms also serve as launch points for associated
10 **IDP** media. Through user interactive input **804**, the shopper launches video and audio presentations about the product and the merchant by clicking on a **PUP** object or menus displayed on a **PUP** object.

PUP2 and **PUP3** mechanisms also serve as portals for online product purchasing and customer tracking transaction systems. When the **PUP** mechanism
15 connects to a **SELL** node's purchasing and customer tracking systems, **PUP2** and **PUP3** displays become the graphical user interface to those systems.

Rendering engine **17** renders **PUP** displays in a scene graph when they are activated. **PUP** displays may be re-positioned by the user or automatically by the application program. As a 2D image overlay, a **PUP2** may move with the object it is
20 attached to as a translation in the plane of the image. As a full 3D object, a **PUP3** may move to any orientation within the 3-space coordinate system of the construction. In the present embodiment, a **PUP3** remains attached to a selected reference point of its associated 3D object and also rotates as a billboard to maintain a consistent orientation relative to the current viewer position. This implementation is analogous to dynamic 3D
25 billboards implemented in 3D graphics visual simulation systems.

In the present embodiment, **SHOP** nodes download media processing engine **11** "client-side" processing components from **SELL** server nodes. Some or all of media processing engine **11** functional components are downloaded over **10**. The selection of components **C-PROG** downloaded depends on the application environment
30 and is configurable by the system. **SHOP** nodes may also import **C-PROG** processing components from other digital data mediums such as CDROM.

SHOP nodes create and integrate 2D and 3D digital environment and product representations and information. Central to their role in a merchandising environment is enabling a shopper to acquire and reconstruct their application

environment and readily integrate and simulate product constructions from **SELL** nodes. In addition, a **SHOP** node may also generate product 3D constructions directly from 2D imagery. When such information is either not available from a product purveyor or is not applicable to the circumstances. A shopper can acquire documented and undocumented
5 digital imagery from sources such as the Internet, digital cameras, and scanners, and transform them into 3D representations. This extremely flexible program and processing distribution model allows processing and data distribution to be efficiently tailored by the requirements of the commerce environment.

SHOP nodes download product-specific 2D digital images **21**, scene
10 graphs and 3D texture-mapped models **20**, and project databases and ancillary digital data **22** from **SELL** nodes or optionally from other **SHOP** nodes over network **10**. Media downloaded as individual components or as **IOP**, **IIP**, and **IDP** packages.

SHOP nodes import user 2D digital images **24** and 3D models **23** from directly from digital acquisition devices, such as digital cameras and scanners. **SHOP**
15 nodes may also download user-specific digital imagery **24** and 3D models **23** from network **10** or other medium such as CDROM. For example, a user might photograph a scene or product with an analog camera and employ a processing service that develops and digitizes film and delivers the digital images to the user via the Internet or CDROM.

SHOP nodes employ the disclosed media integration methods to integrate
20 user generated constructions with downloaded or imported **SELL** node constructions. **SHOP** nodes employ the simulation methods enabling **SHOP** nodes to simulate form and function of **SELL** node products within their environments. In addition to spatial positioning, simulation includes exploration of product size, fit, color, and texture options as well as product functionality (e.g. open-close doors, turn on-off lights, test switches).

25 Several usage scenarios for the disclosed merchandising system are presented.

Example 1

A home furnishings merchant displays items for sale at its e-commerce web site on Internet **10**. The site is enabled with the merchandising system as a **SELL**
30 server node **SN200**. Displayed at the merchant site is the rug item depicted as image **I500** of Fig. 28.

An online Internet shopper visits the merchant **SELL** site with interest in purchasing the rug. From the merchant site the shopper selects an option to visualize the rug in her home. This selection launches the download of a merchant-tailored client-side

version of media processing engine 11 software **S-PROG** from the merchant **SELL** site to the shopper computer system on network 10. This transaction enables the shopper as a **SHOP** node with media processing engine 11 software components **C-PROG**.

The shopper seeks to visualize rug **I500** in her living room depicted in Fig. 18(a) image **I200**. The shopper acquires image **I200** with a digital camera and downloads it as user data 24. For a wider field-of-view of the living room scene, the shopper takes multiple snapshots and downloads them as user data 24. In the latter case, the shopper employs the image mosaic processing features of media processing engine 11 to stitch the images together.

The shopper selects rug image **I500** from the **SELL** site, triggering a download of merchant product media from the **SELL** computer to the **SHOP** computer. The merchant **SELL** node transfers an intelligent image package **IIP** for the rug product that includes three product images 21, one for each rug color scheme offered, six size parameters denoting the dimensions of three rug sizes offered, and PC graphic **PG6**. The **SELL** node also transfers an Intelligent Ancillary Data Package **IDP** containing **PUP2-10**. No 3D object geometry 20 is transferred from **SELL** site to **SHOP**; rug geometry is generated by the **SHOP** node.

The shopper also takes her digital camera to a local retail store and acquires artwork image **I502** of Fig. 28 to visualize it in the same living room with the rug. She imports image **I502** from the digital camera into her computer as user data 24. As a **SHOP** node, through user-interactive input 804, the shopper employs media processing engine 11 configured in image collage construction mode to produce the collage of scene **I200** with rug image **I500** and artwork image **I502**, resulting in image **I401**, shown in Fig. 30.

To view the rug options downloaded with the **IIP**, the **SHOP** node application allows the shopper to click on collage product items to scroll through the insertion of the three pattern options. The **SHOP** node also scales the collage geometry according to the merchant supplied size parameters, allowing the user to select and visualize the various rug size offerings. When selected, **PUP2-20** is displayed to provide online product information and launch the **SELL** node purchasing transaction system.

Example 2

The shopper of Example 1 wants to interactively simulate placement of the rug in various positions on the floor within the living room scene. The shopper employs the system 3D scene construction mode.

The previously described process flow of Fig. 39, with the integration of "rug" object of Fig. 28 image **I500** within scene **I200** of Fig. 18(a) and "true-to-scale" object insertion of Fig. 40, is executed. In her living room, the shopper measures the distance between the back wall of the room and the marble fireplace base as well as the combined width of the two right French doors. The shopper aligns PC graphic **PG1** as shown in Fig. 18(c) image **I200** and enters the measured values for the width and length parameters of PC structure **PS20**. The scene construction becomes calibrated to the true dimensions of the shopper's living room.

To place the rug on the floor of the room, the shopper selects point **VF5** on the rug in image **I500** and anchor point **933** on the floor in image. The system automatically places and dimensions the rug on the floor with the true rug dimensions downloaded with the merchant **IIP**. Using the **IIP** information and the system interactive simulation functions, the shopper interactively repositions the rug to various locations on the floor and scrolls through the various rug sizes, patterns, and colors. The system automatically and seamlessly interchanges **IIP** supplied shape parameters, texture maps, and color data.

Example 3

A shopper of home furnishings visits a merchant e-commerce web site on network **10**. The merchant site is enabled as a **SELL** server node **SN200**. The shopper selects an option at the merchant site to visualize products in his home. This selection launches the download of a merchant-tailored media processing engine **11** software **S-PROG** from the merchant **SELL** site to the shoppers' computer system on network **10**. This transaction enables the shopper as a **SHOP** node **CN100** with media processing engine **11** software **C-PROG**.

Displayed at the merchant site is pine storage box **91** depicted in Fig. 44 image **I901**. The shopper selects image **I901** and the **SELL** node transfers an **IOP** and an **IDP** for the product to the shopper **SHOP** node. The **IOP** transferred contains the product scene graph, geometric structures, camera models, texture map imagery, and parametric shape and function parameters. The **IDP** contains graphic information display **PUP3-30**.

The shopper visits web site of another merchant on network **10**. The second merchant site is also enabled as a **SELL** server node **SN200**. Displayed at the merchant site is CD cabinet **90** depicted in Fig. 44 image **I900**. The shopper selects

image **I900** and the merchant **SELL** node transfers an **IOP** and an **IDP**, including **PUP2-20**, for the product.

The shopper visits a third web site on network **10**. At that e-commerce site, the merchant displays wood cabinet **93** as image **I903** of Fig. 45. This merchant site is not enabled as an **SELL** node, so the shopper downloads only image **I903** using the image download facility of his web browser. The shopper manually records the advertised dimensions of the product for future manual entry into the **SHOP** node system.

The shopper takes a picture of the room he has in mind for the products. The shopper acquires scene image **I700** of with a conventional camera and has the film developed through a service that provides digital images returned over the Internet. The shopper downloads his image **I700** as user data **24** over network **10** from the film service.

The shopper visits a local retail store and acquires photographs of the mirror product of image **I904** of Fig. 45 and the artwork product of image **I502** Fig. 28. No dimensions for these items are obtained. These photographs are processed into digital images and downloaded into the **SHOP** node in the same manner as scene image **I770**.

Employing the **C-PROG** 3D scene construction program downloaded from the first merchant **SELL** node, the shopper produces the 3D construction from scene image **I700**. The shopper supplies actual room dimensions that correspond to the dimensions **S1** and **S2** of PC structure **PS10**. The room scene geometry and camera model are calibrated to true scale. If a greater extent of the room scene is desired, the shopper would acquire more images of the room and continue with the 3D scene construction process in multi-image mode.

Employing **C-PROG**, 3D object construction program downloaded from the first merchant **SELL** node, the shopper constructs a parametric 3D texture-mapped model for brown cabinet **93**. The parametric model is produced true scale using the product dimensions recorded by the shopper.

The shopper then uses the construction "true-to-scale" object insertion process to insert **SELL** node supplied 3D models for pine storage box **91** and CD cabinet **90** and shopper constructed 3D model for brown cabinet **93** onto the floor of the shopper constructed 3D scene. The "force-fit" insertion process is employed to place mirror **94** and the artwork of image **I502** on the walls of the 3D scene construction. This entails the user placing a PC graphic in each product image as the product source regions and a corresponding PC graphic on the wall locations desired as the destination regions. For the placement of mirror product **94**, the system also employs the rendering engine **17**

projective alpha channel masking and composition layering to produce the detail of the wrought iron frame.

5 The selected products are then simulated in 3D in the shopper's room scene, with the user interactively navigating the scene, repositioning the products, and exploring the functional **IOP** components. Fig. 46 images **I910**, **I920**, **I930**, and **I940** show several frames of a real-time interactive 3D simulation rendered by the **SHOP** node. The two cabinets and the pine box are placed at various positions on the floor throughout the 3D room scene. The mirror and artwork products remain attached in place on the walls. In image **I910**, the mirror is moved on the wall to another location (not visible).

10 Fig. 48 (image **I990**) is a frame of the output display showing the deployment of **PUP2-20** attached to the CD cabinet and **PUP3-30** attached to the pine storage box. In the present example, the shopper clicks on the **PUPs** to view and hear about the product specifications, pricing, and options. To order a product, the user clicks on a **PUP** and the system launches the order transaction system of the attached **SELL**
15 node.

WHAT IS CLAIMED IS:

- 1 1. A method of interactively determining a camera position in a three-
2 dimensional space from a two-dimensional image of objects in the three-
3 dimensional space, the method comprising the steps of:
4 selecting an object in the space to be a reference object;
5 identifying a polygon in the image that corresponds to a planar facet of the
6 reference object in the space;
7 identifying at least one dimension of an edge of the reference object; and
8 calculating camera parameters including a camera position from the polygon and
9 the dimension.
- 1 2. The method of claim 1, wherein the step of calculating comprises:
2 identifying parameterized geometric primitives in the space;
3 determining the elements of the primitives, wherein an element is a spatial
4 structure projectable onto the image;
5 mapping features of the image to the elements to form correspondences; and
6 solving for an objective function that minimizes an aggregate error between
7 features of the image and projections of elements onto the image.
- 1 3. A method for generating remote presentations of products in situ for a user
2 comprising the steps of:
3 a) prompting the user to acquire a digital image of a space in which a product is
4 to be viewed in context;
5 b) accepting a product representation representing a product for which a
6 three-dimensional geometric model exists or can be created;
7 c) determining at least one dimension reference, wherein a dimension reference is
8 a measurement of a distance in the space corresponding to a separation of
9 two points on the digital image;
10 d) calculating, from the image, the at least one dimension reference and reference
11 information, camera parameters for a camera in the space from which the
12 image was captured, wherein the camera parameters include at least a camera
13 position and a focal length;
14 e) accepting an input of a product location, the product location being a location
15 in the space where the product is to be displayed in situ;

16 f) transforming the geometric model of the product based on at least the camera
17 position and the product location to form a transformed geometric model;
18 and
19 g) combining the transformed geometric model and the digital image to form a
20 modified image of the space where the modified image has been modified to
21 show the identified product in situ in the image with a proper proportion and
22 perspective.

1 4. The method of claim 13, wherein the step of accepting a product
2 representation comprises the steps of:
3 prompting the user to identify a product of interest from a set of products;
4 searching a collection of product representations to locate a member of the
5 collection that matches the product identified by the user; and
6 accepting the matching product representation.

1 5. The method of claim 14, further comprising a step of repeating steps b), e) and
2 f) for second and subsequent selected products.

1 6. The method of claim 13, wherein the step of accepting a product
2 representation includes a prior step of prompting the user to acquire a
3 three-dimensional geometric model for a product of interest to the user.

1 7. The method of claim 13, further comprising a step of repeating step a) for
2 second and subsequent images of the space and using each of the provided
3 images.

1 8. The method of claim 13, wherein the modified image of the space is a
2 two-dimensional view of a three-dimensional geometric model, the method
3 further comprising a step of moving a camera position of the modified image
4 of the space to simulate moving around in the space.

1 9. The method of claim 13, wherein the step of prompting the user to identify the
2 product from a set of products is performed using a commerce server that
3 serves product models and further comprising a step of transmitting the
4 digital image to the commerce server.

- 1 10. The method of claim 13, wherein the step of prompting the user to identify
2 the product from a set of products is performed using a commerce
3 application that receives product models and further comprising a step of
4 providing the digital image to the commerce application.
- 1 11. The method of claim 13, wherein the camera parameters include camera
2 position, camera rotation, focal length and center of projection.
- 1 12. The method of claim 13, wherein the reference information includes
2 correspondences between two-dimensional image features and
3 three-dimensional structures.
- 1 13. The method of claim 13, wherein the step of determining the at least one
2 dimension reference is a step of inputting the at least one dimension
3 reference, wherein a dimension reference is a measurement of a distance in
4 the space corresponding to a separation of two points on the digital image.
- 1 14. The method of claim 13, wherein the step of determining the at least one
2 dimension reference is a step of assuming a default scale and using the
3 default scale to determine the at least one dimension reference.
- 1 15. The method of claim 13, wherein the three-dimensional model for a product
2 is a planar representation of an object and a texture map to be applied to a
3 surface of the object.
- 1 16. A commerce server for generating remote presentations of products in situ
2 comprising:
3 product image storage for storing product representations, wherein a product
4 representation is at least a product image taken of a three-dimensional
5 product;
6 means for receiving at least one digital image of a space in which a product is to
7 be viewed in situ;
8 space image storage for storing the at least one digital image of the space;

9 parameter storage for storing at least one dimension reference, wherein a
10 dimension reference is a measurement of a distance in the space represented
11 as a line segment on the digital image;
12 a photogrammetric modeling engine having inputs to receive an image and
13 geometric primitives mapping from the space onto the image and having an
14 output to output the camera parameters of a camera in the space with which
15 the image was captured;
16 means for receiving an indication from a client identifying one or more product
17 from a set of products from the product image storage;
18 inputs for receiving one or more product location, a product location being a
19 location in the space where the product is to be in situ;
20 a visual reconstruction engine having an input to receive the digital image of the
21 space from the space image storage, an input to receive camera parameters
22 for the digital image from the photogrammetric modeling engine, an input to
23 receive one or more product representation for selected products as indicated
24 by the means for receiving an indication, and an output for outputting a
25 geometric model of elements of the space including the selected products;
26 and
27 a renderer for rendering a combination of geometric models of the one or more
28 product and the space, using a set of camera parameters common to each.

1 17. An apparatus for generating a three-dimensional geometric model from at
2 least one two-dimensional image of a three-dimensional space having objects
3 therein, the apparatus comprising:
4 a photogrammetry engine with an image input for accepting the at least one
5 two-dimensional image and a primitives output for outputting primitives and
6 parameters that describe geometric elements of the objects in the image; and
7 a solid modeler with a primitives input for inputting primitives and parameters
8 output by the photogrammetry engine and a model output for outputting the
9 geometric model, wherein the solid modeler further includes means for
10 modeling an object in the space with a primitive shape or a mathematical
11 operation of more than one primitive shape.

- 1 18. A method for generating presentations of products in situ, wherein an in situ
2 presentation includes a composite image showing one or more products in a
3 space, the method comprising the steps of:
4 a) inputting a scene digital image of the space, wherein the scene digital image is
5 an image of the space captured by an image capture device positioned in the
6 space at a capture position and having a capture focal length;
7 b) calculating, from the image, capture parameters for the image capture device in
8 the space, wherein the capture parameters include at least a representation of
9 the capture position and a representation of the capture focal length;
10 c) inputting a product representation that represents a product being considered
11 for placement in the space;
12 e) accepting an input of a product location, the product location being a location
13 in the space at which the product is being considered;
14 f) transforming at least one of the scene digital image and the product
15 representation wherein a transformed image is an image transformed
16 according to the image's associated capture parameters; and
17 g) combining the scene digital image and the product representation, as
18 transformed in the step of transforming, to form a combined image of the
19 space where the combined image shows the product in situ in the scene in the
20 combined image with a proper proportion and perspective.
- 1 19. The method of claim 28, wherein the product representation includes a
2 texture map associated with the product.
- 1 20. The method of claim 28, wherein the product representation includes at least
2 a product digital image, captured by a product image capture device
3 positioned to capture a digital image of the product.
- 1 21. The method of claim 30, wherein the product representation includes a
2 capture position, capture angle of rotation and focal length.
- 1 22. The method of claim 30, wherein the product representation includes product
2 image capture parameters including at least a representation of the position
3 of the product image capture device when the digital image of the product
4 was captured.

- 1 23. The method of claim 32, wherein the product image capture parameters
2 include projections of geometric elements from the product onto the product
3 digital image.
- 1 24. The method of claim 28, wherein the capture parameters for the image of the
2 scene include projections of geometric elements from the scene onto the
3 scene digital image.
- 1 25. The method of claim 28, wherein the capture parameters for the image of the
2 scene include an angle of rotation for the image capture device in the space.
- 1 26. The method of claim 28, wherein the step of inputting a product
2 representation is preceded by the steps of:
3 capturing a product digital image using the product image capture device; and
4 calculating, from the product digital image, product image capture parameters
5 that include at least a representation of the product image capture position
6 and a representation of the product image capture focal length.
- 1 27. The method of claim 28, wherein the step of transforming results in the one
2 or more transformed digital images sharing common capture parameters, the
3 common capture parameters including at least a capture position.
- 1 28. The method of claim 28, further comprising a step of prompting the user to
2 identify the product from a set of products for which a three-dimensional
3 geometric model exists or can be created.
- 1 29. The method of claim 28, further comprising a step of inputting at least one
2 dimension reference for one or both of the scene digital image and the
3 product representation, wherein a dimension reference is a measurement of a
4 distance in space corresponding to a separation of two points on the digital
5 image or representation with which the dimension reference is associated.
- 1 30. The method of claim 28, further comprising the step of repeating the step of
2 combining to form a further combined image of the space and a plurality of
3 products, where the further combined image shows the plurality of products

4 in situ in the scene with each product having a proper proportion and
5 perspective.

1 31. The method of claim 28, wherein the step of inputting a product
2 representation is followed by a step of calculating, from the product digital
3 image, product image capture parameters that include at least a
4 representation of the product image capture position and a representation of
5 the product image capture focal length.

1 32. A method for generating a combined image that simulates a product being
2 positioned at a location where a consumer is considering placing the product,
3 without physically placing the product at the location, the method
4 comprising the steps of:

- 5 a) prompting the consumer to acquire a digital image of the location;
6 b) generating a location representation of the location and geometric elements
7 representing items at the location visible in the digital image of the location;
8 c) prompting the consumer to select a product from among a plurality of
9 products;
10 d) retrieving a product representation for a selected product, wherein the product
11 representation includes at least a digital image of the product and a
12 representation of the position of a product image capture device when the
13 digital image of the product was captured.

1 33. The method of claim 42, wherein the location representation includes
2 location capture parameters of a location capture device, wherein the location
3 capture parameters include at least a representation of a position of the
4 location capture device.

1 34. The method of claim 42, further comprising the steps of:
2 e) prompting the consumer to indicate where, at the location, the product is to be
3 considered; and
4 f) combining the location representation and the product representation after
5 transforming at least one of the representations to form the combined image
6 showing the product in situ with a proper proportion and perspective.

- 1 35. The method of claim 42, wherein the product representation includes at least
2 a three-dimensional geometric model and a texture map.
- 1 36. The method of claim 42, wherein the method is performed by a commerce
2 server and a consumer computer, the method further comprising the steps of:
3 e) sending a commerce application from the commerce server to the consumer
4 computer;
5 f) executing the commerce application on the consumer computer, wherein the
6 commerce application performs steps a) and c);
7 g) using the commerce application to model geometric elements visible in the
8 digital image of the location; and
9 h) generating capture parameters for the digital image of the location from the
10 geometric elements using the commerce application, the capture parameters
11 including a capture location and a focal length.
- 1 37. The method of claim 42, wherein the method is performed by a commerce
2 server and a consumer computer and wherein the step of retrieving the
3 product representations is a step of retrieving the product representations
4 from the commerce server.
- 1 38. The method of claim 42, wherein the method is performed by a commerce
2 server and a consumer computer and wherein the step of retrieving the
3 product representations is a step of retrieving the product representations
4 from a product representation server.
- 1 39. A method of combining a plurality of two-dimensional images of
2 three-dimensional spaces into a combined image, comprising the steps of:
3 receiving the plurality of two-dimensional images;
4 using a photogrammetry engine to identify primitives and parameters that
5 describe geometric elements of the objects in the plurality of
6 two-dimensional images;
7 identifying common objects common to more than one of the plurality of
8 two-dimensional images;

9 determining camera models such that the common objects are substantially
10 coincident in a common image plane, thereby forming a combined geometric
11 model; and
12 generating an image of the combined geometric model.

1 40. The method of claim 49, further comprising a step of using a solid modeler
2 with a primitives input to generate a geometric model for each
3 two-dimensional image from primitives and parameters output by the
4 photogrammetry engine.

1 41. A commerce application for generating remote presentations of products in
2 situ, using a client-server system, the commerce application comprising:
3 means for receiving product representations, wherein a product representation is
4 at least a product image taken of a three-dimensional product;
5 means for receiving a space representation comprising at least one digital image
6 of a space in which a product is to be viewed in situ;
7 space representation storage for storing the space representation;
8 parameter storage for storing at least one dimension reference, wherein a
9 dimension reference is a measurement of a distance in the space represented
10 as a line segment on the digital image;
11 a photogrammetric modeling engine having inputs to receive an image and
12 geometric primitives mapping from the space onto the image and having an
13 output to output the camera parameters of a camera in the space with which
14 the image was captured;
15 inputs for receiving one or more product location, a product location being a
16 location in the space where the product is to be in situ;
17 a visual reconstruction engine having an input to receive the digital image of the
18 space from the space representation storage, an input to receive camera
19 parameters for the digital image from the photogrammetric modeling engine,
20 an input to receive one or more product representation for selected products
21 as indicated by the means for receiving an indication, and an output for
22 outputting a geometric model of elements of the space including the selected
23 products; and

24 a renderer for rendering a combination of geometric models of the one or more
25 product and the space, using a set of camera parameters common to each.

1 42. The commerce application of claim 51, wherein the means for receiving
2 selected product representations comprises:
3 means for receiving an indication from a client identifying one or more product
4 from a set of products; and
5 means for retrieving selected product representations from a product
6 representation storage.

1 43. The commerce application of claim 51 comprising:
2 a client system including the space representation storage, the parameter storage,
3 the photogrammetric modeling engine, the visual reconstruction engine and
4 the renderer; and
5 a server system including the product representation storage.

1 44. The commerce application of claim 51 comprising:
2 a client system including the space representation storage, the parameter storage
3 and the renderer; and
4 a server system including the product representation storage, the
5 photogrammetric modeling engine, and the visual reconstruction engine.

1 45. The commerce application of claim 51 comprising:
2 a client system including the space representation storage and the parameter
3 storage; and
4 a server system including the product representation storage, the
5 photogrammetric modeling engine, the visual reconstruction engine and the
6 renderer.

1 46. The commerce application of claim 51 comprising a server system including
2 the space representation storage and the photogrammetric modeling engine.

1 47. A method of generating an image of a simulated space, wherein the space is
2 simulated in that it shows an object placed in a scene, where the object is a
3 physical object and the scene is a physical location, the method comprising
4 the steps of:

5 acquiring one or more images of the scene, wherein the scene does not contain, at
6 the time of acquisition, the object at a desired object location in the scene;
7 generating a scene representation that includes a model of an image acquisition
8 device that captured at least one of the one or more scene images acquired in
9 the step of acquiring one or more images of the scene, the model including at
10 least a representation of a position of the image acquisition device in a space
11 containing the at least scene image when the at least one scene image was
12 captured;
13 acquiring an object representation of the object that is to be simulated in the
14 scene, where the object representation is at least an image of the object; and
15 combining the scene representation and the object representation to form the
16 image of the simulated space.

1 48. The method of claim 57, wherein the object representation includes an image
2 taken from an image capture device.

1 49. The method of claim 57, wherein the object representation includes a texture
2 map.

1 50. The method of claim 57, further comprising a step of obscuring a portion of
2 the scene with the object where the object representation is constrained such
3 that the positioning or size of the object image is dependent on the
4 positioning or size of an object present in the scene.

1 51. The method of claim 60, wherein the object representation comprises an
2 object image and a geometric model where the geometric model of the object
3 corresponds to a geometric model of an existing object in the scene and the
4 simulated space is a simulation of the replacement of the existing object with
5 the object represented by the object representation.
